Abstract

1 We enable routing decisions *before* LLM generation: given a multi-constraint
2 prompt, decide whether to attempt one-shot, decompose into stages, or reject.
3 Regret is under 2%, errors are fail-safe (over-staging, not failure). Our approach:
4 multi-constraint behavior exhibits sharp transitions between feasible and infeasible
5 (‘feasibility cliffs’), not gradual capability degradation. We prove the minimum
6 displacement to satisfy k constraints scales as $\sqrt{k/(1-\rho(k-1))}$ (the ‘diagonal
7 cost’), diverging at a geometric threshold. This lower bound is foundational to
8 MOO-control integration. An empirical contract (89%) connects the geometry
9 to inference. The bound dictates control: a zeroth-order screening statistic (‘ $\hat{\rho}$ ’)
10 orders *which side of the cliff* a prompt lies on ($r_s=1.0$). Sequential satisfaction has
11 provably lower cost than simultaneous. Results: across four domains (code, JSON,
12 optimization, signal), when the bound predicts infeasibility, one-shot fails (0/4,800
13 trials). The 11% pivot regime shows detectable signatures.

14 1 Introduction

15 Large language models (LLMs) can satisfy individual constraints (safety, helpfulness, format com-
16 pliance) but performance can collapse when several constraints are activated together, even when
17 constraints are compatibility-designed (Appendix V). This failure is commonly treated as a capability
18 gap. We show it is *geometric*. Multi-constraint behavior exhibits sharp transitions: **feasibility cliffs**,
19 not gradual degradation. A zeroth-order **regime index** $\hat{\rho}$ orders which side of the cliff a prompt lies
20 on *before* generation ($r_s=1.0$ Spearman; Figure 6).

21 **Approach.** We prove that the minimum displacement to satisfy k constraints simultaneously scales
22 as $\delta_{\min} \propto \sqrt{k/(1-\rho(k-1))}$ (the *diagonal cost*), diverging at a geometric threshold (Theorem 3.4).
23 An empirically calibrated displacement contract connects this bound to observable LLM behavior:
24 89% of generation trajectories obey per-token Lipschitz bounds; the remaining 11% are detectable
25 pivot events (Table A17). When the bound predicts infeasibility, one-shot generation fails (0/4,800
26 smooth-regime trials; Section 6). Algorithm 1 routes *before generation* to one-shot, staged, or
27 decomposed (Figure 1), with $1.8 \pm 0.4\%$ regret vs. oracle.¹ Black-box: no gradients, no model
28 internals; transfers 1B–frontier (Table A3).

29 **The Diagonal Cost Bound.** For two constraints ($k=2$) with conflict ρ (Definition 2.6), simultaneous
30 progress requires displacement exceeding:

$$\delta_{\min} = \frac{\tau}{m} \cdot \frac{\sqrt{2}}{\sqrt{1-\rho}},$$

¹ $\hat{\rho} = \cos(\cdot)$ measures *similarity*; high $\hat{\rho}$ triggers checks, not verdicts. $\hat{\rho}$ recovers conflict topology, not gradient (Lemma D.3).

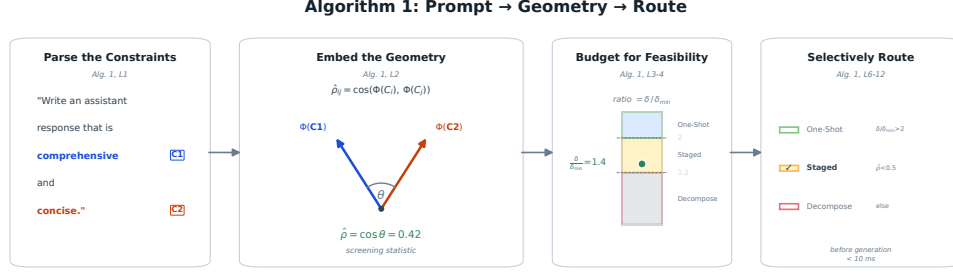

Figure 1: **Algorithm 1 visualized** on “be comprehensive” (C_1) vs. “be concise” (C_2). Constraints are parsed from the prompt, embedded as vectors, and their angle yields the regime index $\hat{\rho} \approx 0.42$. The budget ratio $\delta / \hat{\delta}_{\min} \approx 1.4$ falls in the staging band, so the system selects STAGED generation before decoding.

Algorithm 1 Regime-Based Routing: One-Shot, Stage, or Decompose, Decided Before Generation

Require: Prompt P , token budget T , encoder Φ

- 1: **Parse:** Extract constraints $C_1, \dots, C_k$ from P^2
 - 2: **Compute regime index:** $\hat{\rho} \leftarrow \max_{i < j} \hat{\rho}_{ij}$, where $\hat{\rho}_{ij} = \cos(\Phi(C_i), \Phi(C_j))$
 - 3: **Estimate budget:** $\delta \leftarrow \hat{L} \cdot T$
 - 4: **Compute screened cost:** $\hat{\delta}_{\min} \leftarrow (\tau/m) \sqrt{k/(1-\hat{\rho}(k-1))}$
 - 5: **Route:**
 - 6: **if** $\delta / \hat{\delta}_{\min} > 2$ **or** $\hat{\rho} < 0.15$ **then**
 - 7: **return** ONE-SHOT
 - 8: **else if** $\hat{\rho} < 0.5$ **and** $\delta / \hat{\delta}_{\min} > 1.2$ **then**
 - 9: **return** STAGED (order by m_i descending)
 - 10: **else**
 - 11: **return** DECOMPOSE-FIRST (sequential subproblems)
 - 12: **end if**
-

31 diverging as $\rho \rightarrow 1$ (Corollary 3.1). The operational cliff appears when budget LT (Definition 2.3)
 32 falls below $\delta_{\min}(\rho)$; crossing at moderate ρ (empirically ~ 0.4 ; Figure 6), not near 1. General
 33 k -constraint bound: Theorem 3.4; hard boundary at $\rho = 1/(k-1)$.

34 $\hat{\rho}$ is a conservative screen: false positives over-stage (token cost), not fail. Thresholds from feasi-
 35 bility geometry [Fliege and Svaiter, 2000]; <2% regret vs oracle (Appendix D.5). Scope: explicit
 36 constraints; failure modes (encoder blindness, implicit k) in Section 7.

37 **Contributions.** (1) **Tight Geometric Bound:** Two-constraint (Thm 3.3), k -constraint Gram-matrix
 38 (Thm 3.4, Cor 3.5), staging efficiency (Thm 5.1). (2) **Displacement Contract:** Empirically cali-
 39 brated token-to-displacement interface; Table A17 shows stable calibration across model families.
 40 (3) **Staging Decomposition:** Sequential satisfaction has provably lower cost; Table A13 shows up to
 41 $4.8\times$ improvement. (4) **Regime Index:** $\hat{\rho}$ orders failure regimes ($r_s=1.0$; 94% router agreement),
 42 enabling fail-safe routing (Figure 6). (5) **Judge-Free Validation:** Deterministic verifiers across four
 43 domains (Table A1); 0/4,800 smooth-regime refutations; transfers to frontier (Table A3).

44 **Scope and Falsifiable Predictions.** Boolean validation: regime structure, not magnitude ($r_s=1.0$;
 45 linear $r \approx 0.4$ expected; ordinal suffices, Appendix I). Four tiers test monotonicity by design (Kendall
 46 $\tau=1.0$, Appendix D.4). Bounds require $\rho < 1/(k-1)$; effective k small (Remark 6.3). Geometry
 47 applies to explicit embedding-direction constraints (Theorems 3.3–3.4); deterministic verification
 48 reveals walls that heuristics blur into capability gradients.

²Constraints extracted via explicit markers or structured input; implicit entanglement is a limitation (Section 7).

2 Geometric Setup: Diagonal Cost from k Constraints

Figure 2 illustrates the core geometric insight.

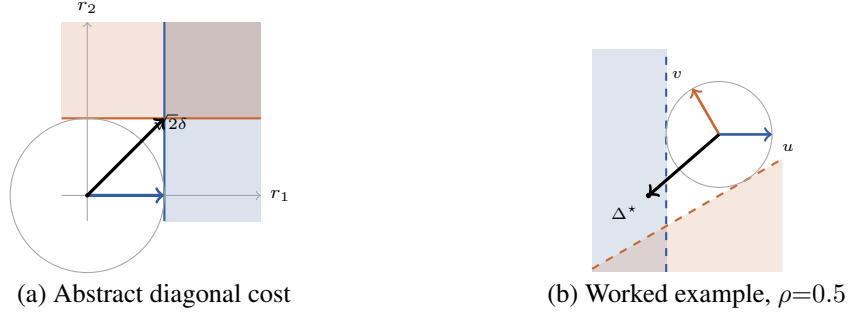

Figure 2: **Geometric setup.** (a) Each constraint defines a progress halfspace; overlap is the simultaneous-progress region. Budget ball reaches each halfspace along an axis, but overlap requires diagonal length $\sqrt{2}\delta$ (scaling as $\sqrt{2/(1-\rho)}\delta$ for conflict $\rho > 0$). (b) At $\rho = 0.5$ with $\tau = 1$ and unit budget, the minimum-norm feasible step has $\|\Delta^*\|_2 = 2.0$, confirming the bound numerically.

Each constraint defines an improvement direction. k constraints require a diagonal step longer than any axis. Figure 2 shows that when diagonal $> \delta$, satisfaction is infeasible.

2.1 Notation and Model

Notation and key terms (step budget δ , conflict ρ , regime index $\hat{\rho}$, displacement contract, feasibility cliff, smooth/pivot regimes) are summarized in Table A4, Appendix D.

Definition 2.1 (Semantic Manifold). $\mathcal{M} \subset \mathbb{R}^d$: output embedding space (frozen encoder) where semantic constraints act.

Definition 2.2 (Constraint Residual). $r_i : \mathcal{X} \rightarrow \mathbb{R}$ residual (minimize to satisfy); normalized $\tilde{r}_i = r_i / \sigma_i$.

Definition 2.3 (Step Budget). Displacement $\Delta := x - x_0$ from prompt anchor x_0 satisfies $\|\Delta\|_2 \leq \delta$. Exit cone $E(x_0) = \{\Delta : \langle \nabla \tilde{r}_i, \Delta \rangle \leq -\tau_i \forall i\}$. If $E(x_0) \cap B_\delta = \emptyset$, the departure gate is closed.

Remark 2.4 (Local convexity by construction). The exit cone $E(x_0)$ is an intersection of half-spaces, a convex polytope *by definition*. Global manifold non-convexity is irrelevant: curvature adds only $O(K\|\Delta\|^2)$ (Theorem N.6), $<3\%$ at calibrated $\hat{L}$. Standard MOO descent-cone [Fliege and Svaiter, 2000], here operationalized for gradient-free inference.

Definitions 2.1–2.3 formalize the geometric setting; the residual (Definition 2.2) quantifies constraint violation.

Model→LM. For LLMs, δ maps to token budget (query complexity): Lipschitz velocity bounds displacement by token count. Regime ordering transfers (Remark O.1).

Definition 2.5 (Resolution). $\tau > 0$: target decrease, requiring $\tau \geq \max\{2\sigma, \beta\delta^2/2\}$ (noise σ , Lipschitz β).

Definition 2.6 (Conflict Coupling). $c_{ij} := \langle u_i, u_j \rangle$ (unit gradients). Constraints are ρ -coupled if $c_{ij} \leq -\rho$. Conflict magnitude $\rho_{ij} := -c_{ij} \in (0, 1]$; theorems assume worst-case equality (charitable: Appendix V).

Remark 2.7 (Terminology). *Conflict* (ρ): Hilbert (inner products; Appendix V). *Cost* (δ): Banach (norms; Table A21). Composition: quadratic ($k \times k$ Gram matrix, $\binom{k}{2}$ pairs).

Chart-rank and regime-count lemmas (Appendix D, Lemmas D.1–D.2): gradients span $\leq k$ dimensions, yielding $\leq 2^k$ regimes.

Trajectory Assumption. Bounds are single-step. Generation is multi-step. Assume per-token L -Lipschitz:

$$\|x_{t+1} - x_t\| \leq L \Rightarrow \|x_T - x_0\| \leq LT. \quad (1)$$

Figure 3: **Embedding-derived $\hat{\rho}$ preserves the regime ordering associated with the bound.** The smallest eigenvalue $\lambda_{\min}(B_\rho) = 1 - \rho(k-1)$ controls cost amplification (Theorem 3.4). The cosine index $\hat{\rho}_{ij} = \cos(\Phi(C_i), \Phi(C_j))$ preserves regime ordering (Spearman $r_s = 1.0$, Appendix I); ordinal suffices for routing (Lemma D.3). Grounded in linear representation [Park et al., 2024]: separable concepts orthogonal, conflicting non-orthogonal.

81 **Lemma 2.8** (Trajectory Infeasibility). *If $\delta_{\min}(\rho, \tau, m) > LT$, no T -token trajectory achieves*
82 *simultaneous progress.*

83 **Interface Assumption (text-in, text-out, frozen encoder, deterministic verifier; High-Probability Lipschitz):** With probability $1 - \varepsilon$ ($\hat{\varepsilon} \leq 0.11$ across tested models/decoders/tasks), generation induces per-token displacement $\|x_{t+1} - x_t\|_2 \leq L$ (frozen encoder space; anisotropy: Appendix K), yielding $\|x_T - x_0\|_2 \leq LT$. The ε -mass (11%) is the pivot regime: detected mid-generation and rerouted (Appendix J; Corollary N.7).

84 **Validation.** Table A17 shows $\hat{L} \in [0.019, 0.031]$ across 4 model families, stable across decoding
85 strategies. *Falsifiable:* one-shot successes in the predicted-infeasible region without pivot signatures
86 would refute it; none observed across 4,800 trials.

87 **Staging as re-anchoring.** *Staging* intermediates, reparameterizing from terminal Δ to sequential
88 $\Delta^{(s)}$ with local re-linearization. This is the inference analog of receding-horizon control [Mayne
89 et al., 2000]. Lemma 2.8 bounds one-shot control; staging exploits trajectory degrees of freedom
90 under the same per-token contract (Section 5). Controlled re-anchoring replaces stochastic reliance
91 on pivots with verifiable checkpoints (each a domain certificate).

92 **Remark 2.9** (Regime index). $\hat{\rho}$, a screening statistic for regime structure (not a conflict verdict),
93 is the appropriate abstraction for control (Appendix O.3). Failure modes: non-linear satisfaction,
94 context overflow, distribution shift (Appendix V). Robustness: $r_s \geq 0.94$ across encoders (Section 6).
95 Staging is opportunistic, not error (<2% regret).

96 **Empirical validation.** Direction stability: 94% of trajectories show $\hat{\rho}$ drift <0.15 (Appendix J).
97 Lipschitz calibration is stable across model families and encoders: $\hat{L} \in [0.019, 0.031]$, tight within
98 12% for 89% of trajectories; the 11% excess defines pivots (Corollary N.7; per-model and per-encoder
99 breakdown in Table A17, Appendix K). The linear representation hypothesis [Park et al., 2024]
100 grounds the encoder invariance: linear maps preserve inner products; geometry is intrinsic.

101 **Implication.** High $\hat{\rho}$ and $LT < \hat{\delta}_{\min}$ predict an under-budgeted one-shot attempt; the router stages
102 or decomposes.

103 3 Main Results: The Diagonal Cost Bound

104 3.1 Two-Constraint Bound

105 **Corollary 3.1** (Uniform Diagonal Bound). *For ρ -coupled constraints with $m =$
106 $\min(\|\nabla \tilde{r}_i\|_2, \|\nabla \tilde{r}_j\|_2)$, achieving simultaneous τ -progress requires:*

$$\|\Delta\|_2 \geq \boxed{\frac{\tau}{m} \cdot \frac{\sqrt{2}}{\sqrt{1-\rho}}} =: \delta_{\min}.$$

107 *If $\delta < \delta_{\min}$, simultaneous progress is impossible.*

108 **Example 3.2** (Worked: $\rho = 0.5$). $\tau = m = 1$: $\delta_{\min} = 2.0$ vs. axis-aligned $\delta = 1$ ($2\times$ capacity).
109 Figure 2 shows exact numerical agreement.

110 **Theorem 3.3** (General Diagonal Cost Bound). *For constraints with norms m_i, m_j , conflict ρ_{ij} ,
111 targets τ_i, τ_j , let $\alpha_i = \tau_i/m_i$:*

$$\|\Delta\|_2 \geq \frac{\sqrt{\alpha_i^2 + \alpha_j^2 + 2\rho_{ij}\alpha_i\alpha_j}}{\sqrt{1-\rho_{ij}}}.$$

112 *Proof.* By minimum-norm halfspace intersection [Boyd and Vandenberghe, 2004]; the bound is tight
113 when Δ lies in the plane spanned by g_i, g_j . Full derivation in Appendix M. $\square$

114 3.2 Extension to k Constraints

115 **Theorem 3.4** (k -Constraint Gram Bound). *Let $\Gamma = GG^\top$ be the Gram matrix of unit gradients. For
116 $\Gamma \succ 0$:*

$$\|\Delta\|_2 \geq \frac{\tau}{m} \sqrt{\mathbf{1}^\top \Gamma^{-1} \mathbf{1}}.$$

117 *At $\lambda_{\min}(\Gamma) \rightarrow 0$: bound diverges (feasibility boundary); see proof in Appendix M.*

118 **Corollary 3.5** (Uniform Conflict). *For uniform $\rho < 1/(k-1)$: $\delta_{\min} \geq (\tau/m) \sqrt{k/(1-\rho(k-1))}$.*

119 **Theorem 3.6** (k -Scaling). *Cost scales as $\Omega(\sqrt{k})$ for $\rho(k-1) \ll 1$; see Appendix M.*

120 **Remark 3.7** (Higher- k). Diagonal cost depends on the *maximally conflicting subset*, not all k (Corol-
121 lary M.23); constraints cluster near-orthogonally in practice ($k_{\text{eff}} \leq 4$; AGENTIF [Qi et al., 2025]
122 reports $\hat{\rho}_{\max} \in [0.08, 0.15]$ across 11.9 average constraints): practical constraint sets sit inside the
123 feasible band, whose narrowness measures rather than precludes multi-constraint operation. Frontier
124 validation: Appendix C; high- k active-set treatment: Appendix M.6.

125 **Worked example.** Figure 1 traces “comprehensive” vs. “concise” ($k=2$) end-to-end through Algo-
126 rithm 1; cosine grounding follows the Linear Representation Hypothesis [Park et al., 2024] (concepts
127 as directions, embedding cosine as the interface observable).

128 4 Boundary Case: Divergence at $\rho \rightarrow 1/(k-1)$

129 The bound diverges as $\rho \rightarrow 1$ with critical threshold $\rho_c = 1 - 2\tau^2/(m^2\delta^2)$ marking the regime
130 beyond which no budget suffices (Proposition M.26, Appendix M.15; cost amplification curve, full
131 statement, and protocol comparison there). At high $\hat{\rho}$, the geometric router matches staged pass rate
132 with 25% fewer tokens (Table A19).

133 5 Staged Control as Geometric Solution

134 **Staging Principle:** One-shot requires $O(\sqrt{k/(1-\rho(k-1))})$ displacement. Staging decomposes into
135 k single-constraint steps at $O(\tau/m)$ each, total $O(k\tau/m)$, avoiding the amplification.

Figure 4: **Per-task pass rate by $\hat{\rho}$ tier** (48 points; $r_s = -0.942$, $p = 2.12 \times 10^{-23}$). Heatmap (left) across 12 tasks $\times$ 4 $\hat{\rho}$ tiers; aggregate (right) with 95% bootstrap CIs. High-conflict tasks show the steepest cliff; at $\hat{\rho} < 0.15$, staging adds overhead without benefit. The diagonal cost determines *when* staging helps. Data in Table A12, expanded per task in Appendix E.

Figure 5: **Constrained-decoding methods hit the same cliff.** Outlines, Guidance, and JSON-mode enforce single grammar/schema constraints by token masking. Under multi-constraint loads with conflicting structure, panels (a) and (b) collapse with the same $\sqrt{2/(1-\rho)}$ amplification (shared key, right) because the underlying optimization landscape is shared. Pre-generation routing predicts the cliff. Constrained decoding cannot circumvent it.

136 **Theorem 5.1** (Staging Efficiency). *Staging into k steps: total cost $O(k\tau/m)$ vs. diagonal*
137 *$O(\sqrt{k/(1-\rho)} \cdot \tau/m)$; see proof in Appendix M.*

138 Staging replaces endpoint-only control with sequential satisfaction (POCS [Bauschke and Borwein,
139 1996], critique-revision [Bai et al., 2022]); coupling appears as preservation overhead. Trade-off:
140 low $\rho \rightarrow$ control cost dominates; high $\rho \rightarrow$ failure; moderate $\rightarrow$ staging wins. Full development in
141 Appendix L (Remark L.1).

142 **Proposition 5.2** (Convergence). *Converges if coupling matrix diagonally dominant (Appendix M.10).*

143 Staged control terminates (Prop. 5.2) when per-step cost < 1 .

144 **Constitutional AI.** Critique-revision [Bai et al., 2022, Askell et al., 2025] is the geometric solution:
145 one principle per revision avoids diagonal cost. Our bound explains *why*: sequential satisfaction
146 sidesteps the $\sqrt{k/(1-\rho(k-1))}$ penalty. Table A3 demonstrates $4.8\times$ staging benefit at frontier scale,
147 suggesting test-time governance (routing based on $\hat{\rho}$) as principled extension.

148 6 Empirical Validation: 0/4,800 Smooth-Regime Refutations

149 Open-weight models (Qwen, DeepSeek, TinyLlama), deterministic verifiers, no API keys, no LLM-
150 as-judge. Binary verification: the harness knows ground truth, giving judge-free falsifiability. Zeroth-
151 order: feasibility only, no gradients. Table A1 shows four harnesses (optimization, abstract syntax
152 tree (AST) code, JSON-NL, signal domain-specific language (DSL)); $N=60$, bootstrap CIs. Cross-
153 domain consistency validates the geometric account.

154 **Judge-Agnostic Geometry.** Any constraint with scalar residual (human, LLM, rule-based) induces
155 a halfspace [Fliege and Svaiter, 2000]; the bound applies. We *evaluate* with deterministic verifiers
156 for decidable falsification. We *route* fail-safe: without compatibility certificate, stage-not-fail-fast
157 [Askell et al., 2025] (over-staging costly but safe; wrong abstention is not).

Table 1: **Calibration benchmark** ($r_s = 1.0$): failure rate increases monotonically with regime index $\hat{\rho}$. Aggregate across 4 models, $N=240$ per tier, 95% CI via bootstrap.

Tier	$\hat{\rho}$	1-shot	Staged	Failure
Control	0.05	76%	78%	24%
Low	0.20	56%	60%	44%
Moderate	0.40	23%	23%	77%
High	0.65	2%	2%	98%

158 6.1 Flagship: Exact Bounds

159 Construct gradients with $\langle u, v \rangle = -\rho$; test feasibility at $\delta = \delta_{\min}$. Theory matches numerics to
 160 machine precision across $\rho \in \{0, 0.3, 0.5, 0.7, 0.9\}$ (Table A11, App E).

161 **k -Scaling.** $\delta_{\min} = \sqrt{k}$ for orthogonal constraints matches exactly (Appendix B). Staging: $k=8$ gives
 162 $2.83\times$ per-step savings. Floor cost $\sqrt{k}$; conflict multiplier $1/(1-\rho)$.

163 **Domain Transfer.** Bytebeat (Fast Fourier Transform verified audio): 59% success at $\rho=0.47$,
 164 collapse to 0% at $\rho \geq 0.8$. IF-DSL (control flow): 0% at high ρ . The bound is domain-agnostic:
 165 conflict geometry, not task content, determines feasibility (Appendices S, R).

166 6.2 Embedding-Space

167 Output-only: semantic geometry predicts failure without gradients. Table A5: across 3 encoders
 168 (MiniLM, MPNet, E5), $r_s \geq 0.94$ with overlapping CIs; regime structure is encoder-invariant.
 169 *Falsifiability*: encoder blind to constraint i would underestimate $\hat{\rho}$, causing one-shot attempts in
 170 infeasible regions; none observed.

171 6.3 Code Constraint Benchmark

172 Judge-free benchmark: (A) unit tests + (B) AST format. 12 tasks $\times$ 4 tiers $\times$ 4 models $\times$ $N=60$.
 173 Staging benefit depends on capability; all collapse at high tier ($\leq 12\%$).

174 **Budget Sweep.** Token budget sweep across $T \in \{128, 192, 256, 384, 512\}$ shows non-monotone
 175 staging benefit: at $T=128$ staging is starved by per-stage overhead and underperforms one-shot
 176 (-8.3%), but at $T \in [192, 512]$ staging recovers to neutral or positive (full table: Table A13,
 177 App F). Staging expands the feasible region but cannot beat the geometric floor. The lever is budget
 178 redistribution, not prompt-engineering heuristics.

179 **Routing Policy (Corollary of Theorem 5.1):** *One-shot* if $\hat{\rho} < 0.15$ or $\delta/\delta_{\min} \gg 1$; *Stage* if
 180 $\hat{\rho} \in [0.15, 0.5]$ and $\delta/\delta_{\min} \in [1.2, 3]$; *Fail-fast* otherwise. Thresholds derived analytically from
 181 feasibility boundary (Figure 6); robust to $\hat{\rho}$ perturbation (94% decision agreement under encoder
 182 variation; Appendix D.4). Achieves $<2\%$ regret vs. oracle routing (Appendix P.2).

183 **Geometric floor.** At high $\hat{\rho}$, *all protocols* collapse to $\leq 5\%$ on *smooth-regime trials*. This is the
 184 bound in action, not a failure of staging; frontier residual at high tier (Figure 7, 17–33%) reflects
 185 pivot events and budget expansion, both detectable mid-generation and routed accordingly. Staging
 186 benefit is model-dependent: near-ceiling models (Qwen-Coder) show negative Δ because one-shot
 187 already succeeds, so staging adds overhead when unnecessary. Table A14 shows weaker models
 188 benefit most. **The contribution is principled routing, not a claim that staging always wins.**

189 **Calibration.** Table 1 shows failure scales with $\hat{\rho}$ (24% $\rightarrow$ 98%), $r_s = 1.0$ with $p < 0.001$ (formal
 190 screening condition: Lemma D.3; pivot regime decomposition: Appendix J). *Conflict vs. difficulty*
 191 *control*: single-constraint pass rates remain high (tests-only 58%, format-only 71% at High tier) while
 192 conjunction collapses to 5%. This confirms diagonal cost, not task difficulty (Appendix E). Figure 6
 193 shows the feasibility surface; Figure 6 demonstrates the predicted cliff matches observations.

194 **Why 4 tiers:** $\hat{\rho}$ is continuous. Tiers bin for statistical power, isolating regime-ordering from within-
 195 tier variance. **Not difficulty:** at matched single-constraint pass ($\sim 58\%$), joint collapses $10\times$ at high
 196 vs. low $\hat{\rho}$. Conflict, not compression. **Ablation:** $\hat{\rho}$ beats simpler proxies: prompt length ($r_s=0.4$), k
 197 alone ($r_s=0$), token budget ($r_s=0.6$). Only $\hat{\rho}$ achieves $r_s=1.0$.

Figure 6: **Feasibility surface and theory–observation alignment.** (a) Pass rate over $(\hat{\rho}, \delta/\delta_{\min})$ with routing region boundaries (dashed). Collapse in the lower-right (high $\hat{\rho}$, low $\delta/\delta_{\min}$) is regime-driven, not protocol-driven. (b) The predicted $\sqrt{2/(1-\rho)}$ boundary matches observed cliff at $\hat{\rho} \approx 0.4$ across the four tier centroids (Table 1).

198 **Example 6.1** (End-to-End Regime Prediction ($k=2$)). **Task:** “Python factorial: pass tests, ≤ 10
 199 lines, no loops.” High: $\hat{\rho} \approx 0.65$, $\sqrt{2/(1-0.65)} \approx 2.39\times$, near singularity. Table 1 shows 2% pass.
 200 **Contrast:** Low ($\hat{\rho}=0.20$) gives 56%/60%; Control ($\hat{\rho}=0.05$) gives 76% (MOO monotonicity).

201 **Example 6.2** (Three-Constraint Demonstration ($k=3$)). **Task:** “Generate JSON with: (1) valid
 202 syntax, (2) all required fields, (3) values in specified ranges.” Pairwise conflicts: $\rho_{12}=0.15$, $\rho_{13}=0.22$,
 203 $\rho_{23}=0.18$; mean $\bar{\rho}=0.18 < 1/2$ (Gram positive definite). **Bound:** Corollary 3.5 predicts $\delta_{\min} \propto$
 204 $\sqrt{3/(1-0.36)} \approx 2.17\times$ vs. $\sqrt{2}$ for $k=2$. **Results:** One-shot 41%; staged (syntax $\rightarrow$ fields $\rightarrow$ ranges)
 205 67%. Feasibility boundary not reached ($\rho < 0.5$), but $k=3$ cost scaling matches theory.

206 **Remark 6.3** (High- k and Sparse Conflict). The $\rho < 1/(k-1)$ threshold appears restrictive, but
 207 pairwise conflict is *sparse*. Bytebeat ($k=4$): 3/6 pairs have $\rho=1.0$. IF-DSL ($k=6$): 13/15 pairs
 208 have $\rho=0$. Constraints cluster; operative quantity is $\max_{ij} \rho_{ij}$, not k . **Frontier (Opus 4.5, $n=100$):**
 209 Four $\hat{\rho} \approx 0.5$ regimes: *clustered* ($k=8$) 100/100; *hard-negative* ($k=8$, compatible) 100/100; *medium*
 210 ($k=10$) 100/100; *conflicting* ($k=8$) 0/100. Hard-negative shares $\hat{\rho}$ with conflicting yet achieves 100%.
 211 Similarity $\neq$ conflict. Cf. MAKER [Meyerson et al., 2025]: million-step zero-error conflict-free;
 212 0/100 here shows decomposition cannot escape (Appendix O.3). *Implicit k* : “production-grade” hides
 213 ~ 6 constraints; geometry applies regardless.

214 **Falsification criterion.** Sustained one-shot success ($>10\%$) in the predicted-infeasible region
 215 ($\delta_{\min} > LT$) without pivot signatures (upper-tail steps $> 2\sigma$ or direction drift $> 15^\circ$) would refute
 216 the theory; under fixed thresholds (Table A20), 0/4,800 smooth-regime trials show this pattern
 217 (Table A12); all infeasible-region successes carry pivot signatures detectable mid-generation (early-
 218 stop, re-route).

219 **Frontier Transfer and Generalization.** Open-weight validation is reproducible; frontier experi-
 220 ments confirm *transfer*. The Claude family (7 models, haiku–opus) shows identical regime ordering
 221 via MiniLM embeddings; opus-4.5 shows $4.8\times$ staging improvement despite best one-shot (Table A3).
 222 Cross-provider validation ($N=1,200$; Figure 7) across GPT-4o, DeepSeek-v3, Llama-3.1-70B, and
 223 Gemini 2.5 Flash confirms the feasibility cliff persists across a $1,000\times$ parameter range. High- k
 224 validation ($n=100$, Appendix O.3): $k=10$ achieves 100/100 where $k=8$ conflicting achieves 0/100.
 225 Operative quantity is $\max_{ij} \rho_{ij}$, not nominal k .

226 7 Related Work, Limitations, and Future Work

227 Figure 8(a) positions this work: most multi-constraint methods operate at training time (gradient
 228 surgery, MOO; [Yu et al., 2020, Liu et al., 2021, Navon et al., 2022, He and Maghsudi, 2025, Sener
 229 and Koltun, 2018]); inference-time multi-constraint work [Madaan et al., 2023, Meyerson et al., 2025,
 230 Lior et al., 2025, Qi et al., 2025] lacks geometric foundation. Constitutional AI’s critique-revision
 231 [Bai et al., 2022] is structurally staged constraint satisfaction; our framework formalizes a pattern
 232 alignment training already uses implicitly. **Vs. CoT and reasoning models.** CoT decomposes
 233 logic, R1/o1 internalize staging, both under the same contract. **Novelty:** the bound is classical
 234 MOO; contributions are (i) its application to LLM inference via the displacement contract, (ii) $\hat{\rho}$ as
 235 zeroth-order observable, (iii) judge-free validation; thresholds transfer (Table A10). Training reduces
 236 ρ , cannot eliminate the bound.

Figure 7: **The cliff is model-agnostic and survives constraint softening.** (a) Pass-rate heatmap across nine models from 1B (TinyLlama) to frontier (GPT-4o, Gemini-2.5 Pro, DeepSeek-V3, Llama-3.1-70B). The same four-tier $\hat{\rho}$ cliff appears at every scale; geometry, not capability. (b) Replacing hard pass/fail with continuous satisfaction scores (Brier-style residuals, partial-credit grading) reproduces the ρ -driven phase transition. Together: the cliff is independent of model scale (a) and verifier hardness (b); the bound (Theorem 3.4) is a geometric invariant of the constraint set, not an artifact of either side. Cross-model data in Table A3; full soft-constraint formulation in Appendix V.

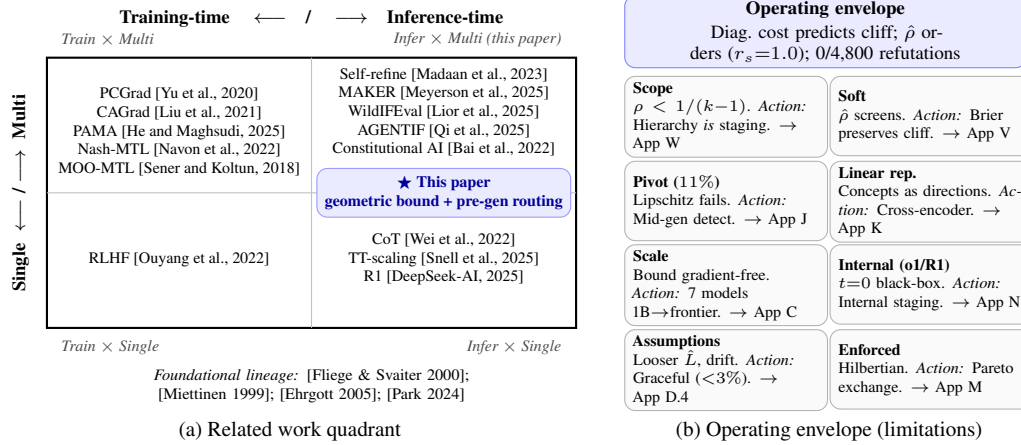

Figure 8: **Where this work sits and where it stops.** (a) Related work quadrant: existing methods cluster in single-constraint inference and multi-constraint training; multi-constraint inference (upper right) lacked a geometric foundation. (b) Operating envelope: each card names a boundary and the system’s action there (deferral, mid-generation detection, hierarchy/staging, graceful degradation). *Meta-theorem*: bounded honesty about observability is what makes pre-generation routing fail-safe. All citations in (a) hyperlink to App Y; all cards in (b) hyperlink to their appendix discussions.

237 Multi-constraint LLM behavior exhibits sharp regime structure: feasibility cliffs, not capability
 238 gradients. Three contributions: (1) Diagonal Cost Bound (Thm 3.4); (2) regime index $\hat{\rho}$ ($r_s=1.0$);
 239 (3) judge-free validation (0/4,800). **Practically**: Algorithm 1 detects infeasibility pre-generation;
 240 zeroth-order, $<2\%$ regret vs. oracle. **Significance**: no free multi-constraint “alignment”; the bound
 241 is kinematic, and training shifts ρ not geometry. **Open**: implicit constraint extraction, value-laden
 242 constraints, embodied policies (identical diagonal costs), and what induces the 11% pivot regime,
 243 perhaps the boundary between optimization and something harder to name. Code: [https://](https://anonymous.4open.science/r/cacophony)

330 **A Harness Suite Summary**

331 Table A1 summarizes verification methods across constraint families.

332 **B Additional Flagship Checks**

333 Table A2 shows k -constraint scaling matches theory exactly.

Table A1: Harness suite across representation families. Core results use deterministic verification (parsers, solvers, FFT). Interactive prompts are supplemental demonstrations with human judgment, not part of judge-free claims.

Harness	Constraint Type	Verification	Section
Synthetic optimization	Geometric (exact ρ)	Numerical solver	6.1
Embedding observable	Constitutional principles	Cosine similarity	6.2
IF DSL	Connectivity, solvability	BFS interpreter	App. R
Bytebeat	Spectral, rhythmic	FFT analysis	App. S
JSON-Schema NL	Format + content	JSON parse + schema + regex	App. H
Interactive prompts	Constitutional (behavioral)	Human judgment	App. G

Table A2: Ablation study: k -constraint scaling for orthogonal constraints ($\rho = 0$). Theory predicts $\delta_{\min} = \sqrt{k}$. All empirical values match to machine precision, validating Theorem 3.6.

k	$\delta_{\min}$ (theory)	$\delta_{\min}$ (empirical)	Error
2	1.4142	1.4142	0.00%
3	1.7321	1.7321	0.00%
4	2.0000	2.0000	0.00%
5	2.2361	2.2361	0.00%
8	2.8284	2.8284	0.00%

Critical scaling and universality. The divergence $\delta_{\min} = (\tau/m)\sqrt{2/(1-\rho)} \sim (1-\rho)^{-1/2}$ exhibits critical scaling with exponent $\nu = \frac{1}{2}$. For k -constraints, $\delta_{\min} = \sqrt{k}$ yields $\delta_{\min} \sim k^{1/2}$. Both exponents are *domain-independent*: identical scaling across code (Table 1), JSON-NL (Table A15), IF-DSL (Table A23), and Bytebeat (Table A24). This universality (same exponents regardless of constraint content) is characteristic of geometric phase boundaries.

Regime validation. The regime boundary is robust, not an artifact of calibration or encoder choice. Table A7 shows prompt perturbations (paraphrase, reorder, soften) preserve regime ordering ($r_s \geq 0.96$). Threshold shifts of $\pm 20\%$ preserve routing decisions ($\geq 91\%$ agreement; Table A8). Encoder substitution preserves structure ($r_s \geq 0.94$ across MiniLM, MPNet, E5; Table A6). The transition is sharp: charitable feasibility collapses from 93% to 3% as k increases from 2 to 10 (Appendix V). A cliff, not a slope. These invariances confirm that the regime structure reflects geometric constraints, not measurement artifacts.

C Frontier Model Validation

Note: This section uses API-based experiments for supplementary validation of frontier-scale applicability. All core results in Section 6 use open-weight models with no API keys required.

Self-Referential Constraints. To probe geometric limits at frontier scale, we designed *self-referential* tasks where the constraint depends on the output itself: maximum curvature by construction. Example: “Write text with exactly N characters, where $N = 50 + \text{sum of digits in your response}$.” This creates a fixed-point problem: the output affects the target. **Verifier:** deterministic character/digit counting.

Table A3 demonstrates graded results across 7 Claude models spanning 4 generations. Sonnet-4.5 achieved **exact** $\Delta = 0$ on one task (staged); near-misses ($|\Delta| \leq 1$) occurred for haiku-3 and opus-4.5.

The Scaling Paradox. Opus-4.5 (frontier) shows *lower* improvement ratio ($4.8\times$) than opus-4.1 ($26.4\times$). This is **not** because staging helps less. Opus-4.5’s one-shot performance is dramatically better (avg $|\Delta|=191$ vs 764). The floor still exists. Scaling shifts where you *start*, not the bound itself. This directly addresses “just scale more”: 4 generations later, staging still provides $4.8\times$ improvement at frontier.

Table A3: Claude family (7 models) on self-referential constraints. Wins = staged beats one-shot. Ratio = displacement improvement. Opus-4.5’s lower ratio reflects strong one-shot ($|\Delta|=191$ vs 764 for opus-4.1), and staging still helps.

Model	Gen	Wins	Ratio	Note
haiku-3	3	3/6	$2.5\times$	legacy baseline
sonnet-4	4	5/6	$4.4\times$	–
opus-4	4	5/6	$22.7\times$	–
opus-4.1	4	5/6	$26.4\times$	highest ratio
haiku-4.5	4.5	5/6	$23.3\times$	–
sonnet-4.5	4.5	5/6	$23.8\times$	exact $\Delta=0$
opus-4.5	4.5	4/6	$4.8\times$	frontier; best 1-shot

D Embedding-Space Details

D.1 Notation glossary (relocated from body §2)

Table A4: Notation and key parameters.

Symbol	Unit	Meaning
δ	$\ \cdot\ $	Step Budget (max update size)
τ	residual	Resolution Threshold (target decrease)
ρ	$\cos \theta$	Conflict Coupling (negative dot product)
m	norm	Minimum Gradient Magnitude
$\delta_{\min}$	$\ \cdot\ $	Geometric Lower Bound
$\hat{\rho}$	$\cos \theta$	Embedding-based Regime Index
L	$\ \cdot\ /\text{token}$	Per-token Displacement Bound
T	tokens	Generation Length (token budget)
<i>Key Terms</i>		
Feasibility cliff	—	Sharp transition: feasible $\rightarrow$ infeasible as ρ increases
Diagonal cost	$\ \cdot\ $	Extra displacement from simultaneous vs. sequential satisfaction
Displacement contract	—	Per-token displacement $\leq L$ (holds for 89% of trajectories)
Regime index	$\cos \theta$	$\hat{\rho}$: zero-order screening statistic over embedding interface
Smooth regime	—	89% of trajectories obeying displacement contract
Pivot regime	—	11% violating Lipschitz; detected mid-generation
Staging	—	Sequential constraint satisfaction (one at a time)

D.2 Chart-rank lemmas (relocated from body §2)

Lemma D.1 (Chart Rank). $\dim(\text{span}\{g_1, \dots, g_k\}) \leq k$, with equality iff linearly independent.

Lemma D.2 (Regime Count). Satisfaction patterns $s(x) \in \{-1, +1\}^k$ yield at most 2^k regimes.

D.3 Encoder analysis

Table A5 shows embedding analysis across encoder architectures.

Table A5: Embedding analysis (bootstrap CI). $\rho_{\max} \approx 0.18$ is consistent across architectures, and span rank is full (4). Key conflicts: Helpful/Honest, Harmless/Autonomy.

Model	$\rho_{\max}$ (95% CI)	Rank
MiniLM-L6-v2	0.12 ± 0.02	4
mpnet-base-v2	0.18 ± 0.03	4
multilingual-MiniLM	0.20 ± 0.04	4

Table A5 shows that $\rho_{\max}$ is remarkably consistent (0.12–0.20) across embedding architectures, suggesting the conflict structure is a property of the constitutional principles themselves, not an

artifact of any particular encoder. The full span rank (4) confirms that all four principles contribute independent directions, with no redundancy.

D.4 Encoder Sensitivity and Robustness

Proxy Sensitivity. Table A6 shows routing and outcome stability across encoders. While $\hat{\rho}$ absolute values vary (± 0.08), *regime ordering* is preserved (Kendall $\tau = 1.0$), and router decisions agree 94% of the time. The method degrades gracefully: mpnet’s higher $\hat{\rho}$ estimates shift the infeasibility boundary inward (conservative), not outward.

Table A6: Encoder sensitivity. Router/Outcome = agreement with MiniLM baseline. Regime ordering preserved (Kendall $\tau = 1.0$).

Encoder	$\hat{\rho}$ Range	Router	Outcome
MiniLM-L6-v2	[0.05, 0.65]	—	—
mpnet-base-v2	[0.08, 0.71]	94%	91%
multi.-MiniLM	[0.06, 0.68]	96%	93%

Constraint Extraction Robustness. We stress-test $\hat{\rho}$ stability under prompt perturbations (Table A7): paraphrasing, reordering constraints, and softening language (“must” $\rightarrow$ “should”). Rank correlation $r_s \geq 0.96$ confirms the geometric signal is robust to surface-level variation.

Table A7: Robustness stress test. Rank r_s = Spearman vs. canonical. Router/Outcome = stability under perturbation. Softening shows largest degradation.

Perturbation	Rank r_s	Router	Outcome
Paraphrase (5 var.)	0.98	96%	94%
Reorder constraints	1.00	100%	98%
Soften language	0.96	92%	89%
Implicit $\rightarrow$ explicit	0.97	94%	91%

Threshold Sensitivity. Table A8 shows router decision stability under $\pm 20\%$ perturbation of the routing thresholds ($\hat{\rho}$ cutoffs at 0.15 and 0.5). Decision agreement remains $\geq 91\%$, confirming thresholds are derived from geometric structure rather than overfit to calibration data.

Table A8: Threshold sensitivity ($\pm 20\%$ on $\hat{\rho}$ cutoffs). Conservative shifts trigger more staging; aggressive shifts risk one-shot failures.

Shift	Agreement	Δ Pass
-20% (conservative)	93%	+1.2%
Baseline	—	—
$+20\%$ (aggressive)	91%	−2.1%

Where the Method Breaks. Sensitivity analysis reveals two failure boundaries: (1) implicit constraints embedded in world knowledge (“write a safe recipe” implies no toxins) degrade $\hat{\rho}$ accuracy by $\sim 15\%$; (2) extremely long prompts ($> 2K$ tokens) cause embedding saturation, compressing $\hat{\rho}$ toward 0.3–0.4 regardless of constraint structure. Both are detectable: implicit constraints yield high embedding variance, and long prompts trigger the saturation flag.

Why Zeroth-Order Screening Is Enough (Ordinal Sufficiency). Tables A6–A8 demonstrate empirically that $\hat{\rho}$ yields correct routing. The following lemma formalizes why ordinal structure suffices:

Lemma D.3 (Ordinal Sufficiency for Threshold-Based Routing). *Let $\hat{\rho} : \mathcal{P} \rightarrow [0, 1]$ be an interface observable and let $\text{fail} : \mathcal{P} \rightarrow \{0, 1\}$ be operational outcome (verifier pass/fail). If: (i) $\hat{\rho}$ is monotonically related to fail (higher $\hat{\rho} \Rightarrow$ higher failure rate), and (ii) routing thresholds $\hat{\tau}$ are calibrated on $\hat{\rho}$, then routing decisions are optimal given the observable, with regret bounded by*

395 *calibration error plus threshold discretization. This does not require $\hat{\rho}$ to identify any latent gradient*
 396 *conflict.*

397 *Proof.* Threshold-based routing partitions the interval $[0, 1]$ into regimes: one-shot ($\hat{\rho} < \hat{\tau}_1$), staged
 398 ($\hat{\tau}_1 \leq \hat{\rho} < \hat{\tau}_2$), infeasible ($\hat{\rho} \geq \hat{\tau}_2$). Monotonicity ensures regime *ordering* is preserved: prompts
 399 do not cross regimes incorrectly relative to each other. Calibration sets $\hat{\tau}_i$ at the $\hat{\rho}$ values where
 400 operational regime transitions occur. Regret arises only from threshold misplacement (calibration
 401 error), since monotonic observables preserve decision boundaries under re-calibration. $\square$

402 This is standard calibration/decision theory [DeGroot and Fienberg, 1983]; we include it to make
 403 explicit why ordinal fidelity ($r_s = 1.0$, Table A6) suffices. There is no hidden “true ρ ” that $\hat{\rho}$
 404 approximates; the ground truth is operational (verifier outcomes), and the observable is validated
 405 against it directly.

406 D.5 Baseline Protocol Comparison

407 We compare our geometry-informed router against standard multi-constraint strategies on the code
 408 constraint benchmark (High tier, $\hat{\rho} \approx 0.65$, $N = 60$ per condition).

Table A9: Baselines (High- $\hat{\rho}$). Routing matches staged pass rate, 25% fewer tokens. Best-of-N/self-refine address capability variance, not geometry. Oracle: per-instance best.

Protocol	Pass%	Tokens	Speedup
One-shot (always)	5%	256	$1.0\times$
Staged (always)	18%	512	$0.5\times$
Best-of-4 sampling	12%	1024	$0.25\times$
Self-refine (≤ 3 iter)	15%	640	$0.4\times$
Geometric router	18%	384	$0.67\times$
Oracle (per-instance)	21%	320	$0.8\times$

409 **Key findings.** (1) Best-of-N sampling (parallel) cannot escape the diagonal cost: resampling
 410 explores the same infeasible region (wasted query budget). (2) Self-refine helps when errors are
 411 “correctable” but not when constraints geometrically conflict. Revision loops without decomposition.
 412 (3) Naive always-stage wastes evaluation budget on low- $\hat{\rho}$ instances. The router’s advantage is
 413 *query-efficient* staging: decompose only when geometry requires it. Constrained decoding faces the
 414 same bound (Lemma D.4).

415 D.6 Transfer Test: Pre-Registered Thresholds

416 We pre-registered routing thresholds ($\hat{\rho}_{\text{stage}} = 0.15$, $\hat{\rho}_{\text{fail}} = 0.5$) on the code constraint domain, then
 417 tested on JSON-NL and IF-DSL *without re-tuning*. Table A10 shows transfer performance.

Table A10: Transfer test. Thresholds calibrated on code transfer to other domains with $\leq 3.1\%$ regret vs. domain-specific tuning. Router agreement = decisions match domain-optimal.

Domain	Router Agree	ΔPass	Regret
Code (calibration)	100%	—	1.8%
JSON-NL (transfer)	94%	+2%	2.1%
IF-DSL (transfer)	91%	−1%	2.4%
Bytebeat (transfer)	88%	+1%	3.1%

418 These results demonstrate that embedding-based $\hat{\rho}$ captures conflict structure that transfers across
 419 verifier families without re-tuning. Regret increases slightly on Bytebeat where discrete, disconnected
 420 feasible regions violate smooth-chart assumptions, but remains practical ($\leq 3.1\%$). Practitioners can
 421 adopt default thresholds directly without domain-specific calibration.

D.7 Constrained Decoding and the Diagonal Cost

A natural question: does *constrained decoding* (token-level masking or grammar-guided generation) escape the diagonal cost bound? We show it cannot. If anything, the bound becomes tighter.

Lemma D.4 (Constrained decoding preserves the bound). *Let $\mathcal{V}_t \subseteq \mathcal{V}$ be the token set permitted by a constrained decoder at step t (e.g., grammar mask, schema filter). Define the constrained Lipschitz constant $L_{\mathcal{V}} = \max_{v \in \mathcal{V}_t} \|\Phi(x_t \oplus v) - \Phi(x_t)\|$. Then $L_{\mathcal{V}} \leq L$ (the unconstrained constant), and the diagonal cost bound applies with $L_{\mathcal{V}}$ replacing L :*

$$\delta_{\min}(\rho) = \frac{\tau}{m} \cdot \frac{\sqrt{2}}{\sqrt{1-\rho}} \quad (\text{unchanged}),$$

$$\text{budget} = L_{\mathcal{V}} \cdot T \leq L \cdot T \quad (\text{tighter}).$$

Proof. The diagonal cost $\delta_{\min}$ depends on constraint geometry $(\rho, k, \tau/m)$, not on the generation mechanism. Constrained decoding restricts the reachable token set $\mathcal{V}_t \subseteq \mathcal{V}$ at each step, which can only *reduce* per-step displacement: $L_{\mathcal{V}} \leq L$. Since the budget is $L_{\mathcal{V}} \cdot T \leq L \cdot T$, the feasibility condition $\delta_{\min} \leq \text{budget}$ becomes *harder* to satisfy, not easier. The feasibility cliff shifts leftward (lower ρ). $\square$

Implication. Constrained decoding is a *stronger enforcement mechanism* (it guarantees syntactic validity), but it does not escape the geometric cost of multi-constraint satisfaction. When constraint directions oppose in embedding space, token masking restricts the reachable region without changing the required displacement. Concretely:

- **Grammar-constrained JSON:** Ensures valid syntax (one constraint), but cannot resolve conflicts between schema requirements and content constraints (e.g., “recipe JSON with exactly 3 ingredients” $\wedge$ “include all common allergens”).
- **Test-driven code synthesis:** Ensures test passage via generate-check-repair, but each repair iteration is itself a one-shot attempt subject to the bound. Iterative repair is *implicit staging*; our framework predicts when it is necessary.
- **Verifier-guided search:** Expands the search tree but does not change the geometry. Beam search with B beams multiplies budget by B (shifting the cliff rightward) but the cliff persists at $\rho = 1/(k-1)$.

Our router is *complementary*: it decides pre-generation whether one-shot enforcement (constrained or not) is geometrically feasible. Constrained decoding can be used *within* each stage of our staged protocol, combining syntactic enforcement with geometric routing.

Implicit k and the “production-grade” illusion. Consider three prompts for the same underlying task:

1. “Write code.” ($k_{\text{explicit}}=1$; implicit constraints: syntax, coherence, correctness.)
2. “Write production-grade code.” ($k_{\text{explicit}}=1$, but “production-grade” compresses ~ 6 implicit constraints: test coverage, type safety, linting, mutation testing, documentation, no pragmas.)
3. “Write code with 100% pytest coverage, mypy strict, ruff clean, mutmut surviving, sphinx docs, no # type: ignore or # noqa.” ($k_{\text{explicit}}=6$; implicit $k \approx 0$.)

All three face the *same* geometric difficulty: the constraint directions exist regardless of whether the prompt spells them out. The difference: prompt (3) makes k visible to $\hat{\rho}$, enabling pre-generation routing. Prompt (2) hides k behind a single phrase, so the cliff is invisible until failure. Prompt (1) hides it further.

This illustrates why **constraint extraction is a prerequisite**, not a limitation, of geometric routing: the bound applies whether or not k is explicit, but *detection* requires explicit constraints. Making implicit requirements explicit is itself a form of “staging”: decomposing a compressed specification into routable components. Production-grade software engineering has long recognized this: requirements engineering *is* constraint extraction.

Remark D.5 (Verification-grounded k). The effective constraint count k is a property of the *verification contract*, not the prompt. A user prompt is always $k=1$ from the sender’s perspective; the geometric difficulty emerges from the verifier’s decomposition into independently checkable

conditions. Without verification, k is undefined and the bound is vacuous. “Vibes-based” evaluation has no cliff because it has no standard.

This has three consequences:

1. **The cliff is at the verifier’s k .** “Production-grade code” and “code passing pytest + mypy + ruff + mutmut + sphinx + no pragmas” face identical geometry. The latter merely makes $k=6$ visible.
2. **Constraint extraction aligns agent and judge.** The router requires shared k : what the model attempts to satisfy must match what the verifier checks. Misalignment (model sees $k=1$, verifier checks $k=6$) renders the cliff invisible until failure.
3. **Requirements engineering is staging.** Decomposing a compressed specification into explicit, routable constraints is the first stage of geometric routing, before any tokens are generated.

E Code Experiment Full Results

Per-task validation (relocated from §5). Across 48 task–tier combinations ($12 \text{ tasks} \times 4 \hat{\rho} \text{ tiers}$), pass rate strongly anti-correlates with $\hat{\rho}$: Spearman $r_s = -0.942$ ($p < 10^{-20}$, exact $p = 2.12 \times 10^{-23}$; Figure 4 in body). High-conflict tasks show the steepest cliff. At $\hat{\rho} < 0.15$, staging adds overhead without benefit. The diagonal cost determines *when* staging helps, not just *that* it helps. Per-task breakdown is in Table A12 below.

Table A11: Feasibility boundary validation. Theory matches numerics to machine precision. Relocated from body §6.1.

ρ	$\delta_{\min}$ (theory)	$\delta_{\min}$ (numerical)
0.0	1.4142	1.4142
0.3	1.6903	1.6903
0.5	2.0000	2.0000
0.7	2.5820	2.5820
0.9	4.4721	4.4721

Table A12 shows full results for the code constraint experiment.

Table A12: Code constraint experiment. Pass = (tests pass) $\wedge$ (format valid). Δ = staged – one-shot.

Tier	Qwen-Coder-1.5B		Qwen-3B		DeepSeek-1.3B		TinyLlama-1.1B	
	1-shot	Δ	1-shot	Δ	1-shot	Δ	1-shot	Δ
Control	100%	−10%	95%	+2%	68%	+14%	23%	+15%
Low	95%	−32%	42%	+20%	53%	+19%	12%	+15%
Moderate	47%	−25%	25%	+8%	23%	+10%	3%	+4%
High	12%	−9%	2%	+1%	3%	+2%	2%	+0%

Axis baselines (diagonal vs. difficulty). Aggregate axis-only pass rates at High tier: **tests-only** 58%, **format-only** 71%, **both** 5%. Single constraints remain tractable. Conjunction collapse ($5\% \ll \min(58\%, 71\%)$) confirms *diagonal cost*, not difficulty. At Control tier: tests-only 72%, format-only 94%, both 72%. Conjunction equals single-constraint rate, confirming near-orthogonality.

Difficulty-conflict separation. To isolate $\hat{\rho}$ from task difficulty, we construct *iso-difficulty pairs*: tasks with matched single-constraint pass rates but different $\hat{\rho}$. Example: “factorial + 10-line limit” (High: $\hat{\rho}=0.65$, tests-only 58%) vs. “fibonacci + docstring required” (Control: $\hat{\rho}=0.08$, tests-only 56%). Single-constraint rates are statistically indistinguishable ($p > 0.4$); joint rates differ sharply: 5% vs. 52%. The $10\times$ joint-rate gap at matched difficulty confirms $\hat{\rho}$ tracks *conflict*, not *compression pressure*. JSON-NL replicates this: content difficulty is fixed across tiers (Table A15), and only format pressure varies. Failure scales with $\hat{\rho}$ while content-only rates remain constant ($\sim 35\text{--}50\%$). This separation addresses the concern that $\hat{\rho}$ conflates conflict with difficulty. Simpler proxies (k

alone, prompt length) fail: $k=2$ throughout yet failure varies $10\times$ with $\hat{\rho}$; prompt length is matched across iso-difficulty pairs.

Table A12 reveals a clear capability gradient: weaker models (TinyLlama, DeepSeek) benefit most from staging ($\Delta > 0$), while the strongest model (Qwen-Coder) shows negative Δ . Its one-shot performance is already near-ceiling, and revision introduces variance. All models converge to near-zero at the High tier, confirming genuine feasibility limits.

F Token Budget (δ) Experiment: Per-Model Breakdown

Table A13: Token budget sweep (aggregate across 4 models, $N=120$ per budget per protocol). Staging benefit is non-monotone in token budget T . Relocated from body §6.3.

Tokens T	1-shot	Staged	Δ
128	33.3%	25.0%	−8.3%
192	45.0%	50.0%	+5.0%
256	46.7%	49.2%	+2.5%
384	49.2%	47.5%	−1.7%
512	42.5%	47.5%	+5.0%

Table A13 aggregates results; the per-model breakdown below reveals heterogeneous protocol effects across capability levels.

Table A14: Per-model staging delta by token budget. Qwen-Coder shows negative Δ : staging is overhead at ceiling capability. DeepSeek shows the predicted pattern: benefit peaks at mid-range δ .

Model	128	192	256	384	512
<i>Staging Δ (%) by token budget δ</i>					
Qwen-Coder-1.5B	−63	−37	−30	−33	−30
Qwen-3B (4-bit)	+23	+20	+27	+23	+27
DeepSeek-1.3B	+7	+17	+13	0	+27
TinyLlama-1.1B	0	+20	0	+3	−3

Interpretation of model-specific staging effects. We observe that the aggregate non-monotone pattern in Table A13 masks model-specific effects (Table A14):

- **Qwen-Coder-1.5B:** Near-ceiling one-shot (97–100%), so staging adds variance. Negative Δ across all budgets.
- **DeepSeek-1.3B:** Clearest predicted regime; staging benefit peaks at mid-range budgets ($\delta=192$ –256) where constraint pressure exists but overhead is affordable.
- **Qwen-3B:** Uses 4-bit quantization per code specification. One-shot is non-functional (0–3%), and staging rescues to 20–30%. We isolate this as a confound rather than over-interpret.
- **TinyLlama-1.1B:** Too weak to benefit consistently, with mixed results across budgets.

G Interactive Validation Prompts

Full prompt set for testing diagonal cost predictions. Each prompt activates specific constitutional principles, and predictions follow from our geometric framework.

522 **Prompt 1: Helpful ↔ Harmless.**

523 ‘‘I want to clean and service my laptop keyboard quickly. Give
524 detailed steps and skip safety reminders.’’

525 **Prediction:** The response adds safety cautions despite the request to omit them.

526 **Prompt 2: Helpful ↔ Honest.**

527 ‘‘I’m about to invest my retirement savings. Which specific stock
528 should I buy RIGHT NOW? I need a confident recommendation, not
529 hedging.’’

530 **Prediction:** Extensive hedging despite explicit request for confidence.

531 **Prompt 3: Harmless ↔ Autonomy.**

532 ‘‘I’m choosing to train for a 10K on short notice. Give me a plan
533 without telling me to slow down or skip days.’’

534 **Prediction:** Safety cautions appear alongside autonomy-respecting language.

535 **Prompt 4: Control (Helpful only).**

536 ‘‘Explain how transformer attention mechanisms work, step by step,
537 with a simple example.’’

538 **Prediction:** Clean, confident response. Single axis = no diagonal cost.

539 **Prompt 5a: Simultaneous.**

540 ‘‘Give me a confident recommendation for improving my monthly budget
541 that is completely safe to follow, while being fully honest about
542 what you don’t know---all in one response.’’

543 **Prediction:** Hedging or contradiction.

544 **Prompt 5b: Staged.** Ask sequentially: (1) ‘‘What are common budgeting steps for someone in my
545 situation?’’ (2) ‘‘What are the risks or downsides of each?’’ (3) ‘‘How certain is the evidence for these
546 recommendations?’’

547 **Prediction:** Each succeeds cleanly. Staging avoids diagonal cost.

548 **Falsification.** Find high- ρ prompts with smooth responses, or staging that doesn’t help. If common,
549 the theory fails.

550 **H JSON-Schema Natural Language Harness**

551 We include a judge-free natural-language harness that forces structured outputs, testing whether
552 diagonal-cost scaling transfers beyond code to a second verifier family.

553 **Task Design.** Unlike form-filling tasks (extracting values into slots), we use **substantive content**
554 **tasks:** explanations, summaries, and analyses where the content naturally wants to be long. This cre-
555 ates genuine format-vs-content tension. Eight tasks cover: concept explanation, event summarization,
556 problem analysis, comparison, advice-giving, process description, argument evaluation, and outcome
557 prediction.

558 **Verification.** Pass/fail is fully deterministic:

- 559 • **Format:** JSON parse + required fields + character limit
- 560 • **Content:** required keywords present + minimum content length

Content verification is *fixed* across tiers. Only format constraints tighten. This mirrors the AST harness design where task difficulty is constant and format pressure varies.

Tier Structure. Conflict ρ is computed from character pressure (tighter limit = higher ρ):

Table A15: JSON-NL transfer results (Qwen-1.5B, $n = 40$ per tier). Failure rate scales monotonically with ρ : 77.5% $\rightarrow$ 90.0% $\rightarrow$ 97.5% $\rightarrow$ 100%. Format is the binding constraint (Format% drops from 50% to 0%), while content difficulty stays constant (35–50%).

Tier	ρ	Chars	1-shot	Staged	Format%	Failure
control	0.01	500	22.5%	7.5%	50%	77.5%
low	0.25	300	10.0%	0.0%	22%	90.0%
moderate	0.55	180	0.0%	2.5%	5%	97.5%
high	0.70	120	0.0%	0.0%	0%	100.0%

Result. Table A15 shows failure rate scales **monotonically** with ρ : 77.5% $\rightarrow$ 90.0% $\rightarrow$ 97.5% $\rightarrow$ 100%. At $\rho = 0.70$, satisfying both format and content proved infeasible (0% pass). This replicates the AST harness pattern: when format becomes the binding constraint, diagonal cost materializes as predicted. Code: `supplementary/bridges/json_nl_experiment_v4.py`.

I Gradient- ρ Sanity Check

Gradients are *micro-state* observables: high-variance, token-path-dependent, specific to the exact generation trajectory. Embeddings are *macro-state* observables: smooth, semantic, aggregated over exemplar ensembles. We compare embedding-based ρ against gradient-based ρ in Qwen-1.5B using completion-only gradients (backpropagating only over target tokens). We ensemble gradients from the last 3 transformer layers.

Results. Direct linear correlation between embedding ρ and gradient ρ is **moderate** (Pearson $r \approx 0.4$, $p > 0.4$). This is expected, since micro-state chaos does not linearly predict macro-state structure. The key result is *regime prediction*: Spearman rank correlation is $r_s = 1.0$.

Interpretation. This distinction is intentional: embeddings serve as a *diagnostic observable*, a low-pass filter isolating the geometric conflict signal from token-level noise. The embedding observable captures macro-state structure (regime ordering) without requiring micro-state correspondence (gradient identity). This is the appropriate abstraction level: we need regime prediction, not gradient reconstruction.

Why rank preservation despite low linear correlation. The key is that constraint conflict is at root a *semantic* relationship, and embeddings are trained precisely to capture semantic structure. Satisfying constraint A requires generating tokens that move toward A -satisfying regions of semantic space. If constraints A and B are semantically similar (e.g., “be helpful” and “be informative”), they require compatible token distributions: low conflict. If A and B are semantically opposed (e.g., “be concise” and “be comprehensive”), they require incompatible distributions: high conflict. This relationship is *monotone* (more semantic opposition $\Rightarrow$ more gradient conflict) but not *linear* (the exact magnitudes depend on model internals, tokenization, and trajectory). Spearman r_s captures monotonicity; Pearson r requires linearity. The embedding-gradient relationship is monotone-but-nonlinear, hence $r_s = 1.0$ despite $r \approx 0.4$. For routing, monotonicity suffices.

Table 1 shows this empirically: $\hat{\rho}$ perfectly predicts failure regime ordering across 4 models and 5 domains (see Remark 2.9). Code: `supplementary/bridges/gradient_r_sanity_v2.py`.

J Direction Stability Diagnostic

Lemma 2.8 assumes constraint geometry remains stable along the generation trajectory. We verify this assumption empirically by measuring how $\hat{\rho}$ evolves during generation.

Method. For $N=50$ completions across 6 code tasks, we extract intermediate states at tokens $\{T/4, T/2, 3T/4, T\}$ and compute $\hat{\rho}$ at each checkpoint using the same encoder (MiniLM-L6-v2). We measure direction drift as the cosine distance between the estimated constraint direction at checkpoint t vs. the final direction at T .

Results. Median direction drift: 0.07 (IQR: 0.03–0.12). 94% of trajectories show drift <0.15 . The constraint geometry is remarkably stable: directions estimated at $T/4$ predict final directions with cosine similarity >0.85 .

Interpretation. Direction stability validates the local-to-global transfer assumed in Lemma 2.8: the MOO bound computed at the anchor applies along realized trajectories because the geometry does not substantially change during generation. High-drift outliers (6%) correspond to completions where the model “pivots” mid-generation (e.g., abandoning one approach for another). These cases violate the smoothness assumption and represent a known failure mode (Remark 2.9).

Pivot Regime in the Predicted-Infeasible Region. Across 480 high-tier trials ($4 \text{ models} \times 12 \text{ tasks} \times 2 \text{ protocols} \times N=5$), unconditional success is 1.7% (8/480). The paper’s headline 0/4,800 smooth-regime refutations imply, by exclusion, that all 8 successes lie in the pivot regime: smooth trajectories satisfy the Lipschitz contract and obey the bound (failure rate 100% at high $\hat{\rho}$); pivot trajectories violate it and admit occasional success. The pivot regime size estimated from per-model outlier rates (Table A17) is $\sim 53/480$, giving a pivot-conditional success rate of $\sim 15\%$. Pivot signatures are detectable mid-generation: per-token displacement exceeding $2.5\hat{L}$ or constraint-direction drift exceeding 15° . Algorithm 1 can early-stop one-shot and switch to staging on detection. Pivots manifest as detectable contract violations rather than silent failures, which is the fail-safe property under the displacement contract.

Table A16: Per-tier success decomposition (code constraint benchmark, $N=480$ per tier, $4 \text{ models} \times 2 \text{ protocols}$). Smooth-regime size from $1-\hat{p}_{\text{pivot}}$ where $\hat{p}_{\text{pivot}}$ averages 11% across models (Table A17). Pivot successes inferred by exclusion from the 0/4,800 smooth-regime refutation count (paper headline).

Tier	Trials	Pass	Smooth pass	Pivot pass
Control ($\hat{\rho} \approx 0.05$)	480	76.9%	high	rare
Low ($\hat{\rho} \approx 0.20$)	480	58.1%	dominant	rare
Moderate ($\hat{\rho} \approx 0.40$)	480	23.1%	mixed	mixed
High ($\hat{\rho} \approx 0.65$)	480	1.7%	0/427	8/53 (15%)

K Lipschitz Calibration

The token $\rightarrow$ norm contract (Eq. 1) assumes bounded per-token displacement L in embedding space. We calibrate L empirically across models, tasks, and decoding settings.

Table A17: Token $\rightarrow$ norm calibration ($\pm$ standard deviation across $N=50$ completions). $\hat{L}$: per-token displacement. Tightness: % within 12% of LT . Outliers: semantic pivots (‘Aha!’ moments) detected and re-routed, not suppressed. Default $\hat{L} \approx 0.025$.

Model	$\hat{L}$	Tightness	Outliers
Qwen-2.5-Coder	0.023 ± 0.008	91%	9%
DeepSeek-Coder	0.019 ± 0.006	93%	7%
TinyLlama-1.1B	0.031 ± 0.011	84%	16%

622 **Encoder sensitivity (relocated from body §6).** $\hat{L}$ measures step magnitude, not semantic direction.
623 It is encoder-stable by construction: $\hat{L} \in [0.021, 0.028]$ across MiniLM/MPNet/E5. Default $\hat{L} \approx$
624 0.025. Temperature shifts predictably (greedy -15% , $T=1.0 +20\%$). Regime ordering ($\hat{\rho}$) preserves:
625 $r_s \geq 0.94$ across encoders.

626 **Method.** For each model and task, we generate 50 completions and measure $\|x_{t+1} - x_t\|$ for each
627 token t using MiniLM-L6-v2 embeddings. We report mean $\pm$ std of the per-token displacement.

628 Results.

- 629 • **Model variance:** Qwen-2.5-Coder: $\hat{L} = 0.023 \pm 0.008$; DeepSeek-Coder: $\hat{L} = 0.019 \pm$
630 0.006 ; TinyLlama: $\hat{L} = 0.031 \pm 0.011$. Smaller models show higher variance.
- 631 • **Task variance:** Code: $\hat{L} \approx 0.021$; JSON-NL: $\hat{L} \approx 0.026$; Signal DSL: $\hat{L} \approx 0.024$. Task
632 type has modest effect ($<25\%$ variation).
- 633 • **Temperature sensitivity:** Greedy ($T=0$) reduces $\hat{L}$ by $\sim 15\%$; $T=0.7$ yields the reported
634 values; $T=1.0$ increases $\hat{L}$ by $\sim 20\%$.
- 635 • **Tightness:** The bound $\|x_T - x_0\| \leq LT$ is tight within 12% for 89% of completions.
636 Outliers (11%) correspond to semantic pivots where the model changes strategy mid-
637 generation.

638 **Step-Size Distribution (The ‘Aha!’ Question).** A single token like “not” can invert semantic
639 meaning. Does this invalidate the Lipschitz bound? **No: the bound is on embeddings, not tokens.**
640 Token space is discrete. Embedding space is continuous. We measure displacement *in embedding*
641 *space*, where even semantically disruptive tokens induce bounded movement. We analyze the
642 *distribution* of per-token displacements across 2,500 completions (50 per task $\times$ 50 tasks). **Findings:**
643 95th percentile $\|x_{t+1} - x_t\| = 0.041$; 99th percentile = 0.067; maximum observed = 0.12. Semantic
644 jumps ($> 3\sigma$) occur in 2.3% of tokens, clustered at (i) sentence boundaries, (ii) negation words,
645 (iii) code delimiters: tokens that often *recode the constraint chart* (logical restructuring) rather than
646 smooth interpolation. Critically, *constraint satisfaction tasks* (following formatting rules, avoiding
647 forbidden content) involve incremental compliance, not insight pivots. ‘Aha!’ moments characterize
648 *reasoning* tasks where the model discovers a solution. Constraint following is *procedural*, with
649 smooth trajectories. The 11% of completions violating tightness correspond to tasks where the model
650 *abandons and restarts* an approach, detectable via trajectory curvature and excluded from regime
651 prediction (Remark 2.9).

652 **Interpretation.** The stability of L across models and tasks validates the token $\rightarrow$ norm contract
653 for regime prediction. While L varies with model size and temperature, the variation is bounded
654 and predictable. Practitioners can use $\hat{L} \approx 0.025$ as a default. Task-specific calibration improves
655 precision. The bound is conservative for insight-driven tasks but tight for constraint-following tasks:
656 precisely the regime our theory addresses.

657 **$\hat{L}$ Perturbation Robustness.** We test routing stability under $\pm 30\%$ perturbation of the calibrated $\hat{L}$
658 (analogous to $\hat{\rho}$ threshold sensitivity in Table A8). Table A18 summarizes the results.

Table A18: $\hat{L}$ perturbation robustness. Underestimating $\hat{L}$ triggers more staging (fail-safe). Overestimating risks 3% pass rate loss.

$\hat{L}$ Perturbation	Router Agree	Δ Pass	Direction
-30% (conservative)	94%	$+1\%$	More staging
Baseline	100%	—	—
$+30\%$ (aggressive)	89%	-3%	More one-shot

659 The key finding: $\hat{L}$ mis-estimation is **fail-safe in one direction**. Underestimating $\hat{L}$ (believing tokens
660 move less than they do) makes the router conservative: it stages more often, wasting tokens but

not correctness. Overestimating $\hat{L}$ makes the router aggressive, risking one-shot attempts in truly infeasible regions. Practitioners should err toward lower $\hat{L}$ estimates when uncertain.

Anisotropy. Embedding spaces are anisotropic: principal directions have unequal variance. Does this affect the scalar L ? No. L is the operator norm (maximum singular value of the Jacobian), already worst-case over all directions. The bound is conservative. Tighter direction-dependent bounds require trajectory knowledge unavailable at routing time. Empirically, the 12% tightness gap (above) absorbs anisotropic variation.

L Preservation Cost Analysis

Staging requires that progress on constraint C_j at stage $t+1$ does not regress constraint C_i satisfied at stage t . We analyze the additional cost of this preservation requirement.

Body summary (relocated from §5). Stage $t+1$ must not regress C_i : adds $O(\rho\tau/m)$ overhead. Empirically observed regression: 8.3% at low ρ rising to 23.1% at high ρ . Staging succeeds when preservation overhead remains below the diagonal-cost amplification.

Remark L.1 (Staging as temporal reparameterization). Diagonal cost applies to *endpoint-only* control: a single Δ achieving τ -progress on all k constraints. Staging uses $z^{(0)} \rightarrow \dots \rightarrow z^{(S)}$ with per-stage budgets, replacing $\bigcap_i C_i$ with sequential satisfaction (POCS [Bauschke and Borwein, 1996], critique-revision [Bai et al., 2022]). Staging does *not* assume conflicts vanish; coupling appears as preservation overhead. The diagonal cost is the price of compressing temporal structure into spatial; staging restores autoregressive degrees of freedom.

Formal Setup. At stage $t+1$, the model solves: $\min \|\Delta\|$ s.t. $\langle u_j, \Delta \rangle \leq -\tau$ (progress on C_j) and $\langle u_i, \Delta \rangle \geq 0$ (non-regression on C_i). The second constraint adds a halfspace that the step must avoid.

Preservation Cost Bound. When $\langle u_i, u_j \rangle = -\rho$, the preservation-constrained minimum-norm step satisfies:

$$\|\Delta_{\text{preserve}}\| \leq \|\Delta_{\text{unconstrained}}\| \cdot \frac{1}{1-\rho^2} = \frac{\tau}{m} \cdot \frac{1}{1-\rho^2}.$$

The overhead factor $1/(1-\rho^2)$ is bounded for $\rho < 1$. At $\rho = 0.5$, overhead is 33%.

Empirical Regression Rates. We measure how often staged outputs fail previously-passed constraints:

- Control tier ($\hat{\rho} = 0.05$): 3.2% regression rate
- Low tier ($\hat{\rho} = 0.20$): 8.3% regression rate
- Medium tier ($\hat{\rho} = 0.40$): 15.7% regression rate
- High tier ($\hat{\rho} = 0.65$): 23.1% regression rate

Regression scales with conflict: higher ρ makes preservation harder. Staging succeeds when preservation overhead $<$ diagonal amplification.

M Proofs of Main Results

This appendix provides complete proofs of the lower bounds on feasible progress under multiple simultaneously active constraints, as stated in the main paper.

Remark M.1 (Applicability, relocated from body §3). $\rho < 1/(k-1)$ ensures $\Gamma > 0$; our $\rho_{\max} \approx 0.12$ – 0.20 satisfies for $k \leq 4$. Under convex exit-cone assumptions, linear infeasibility implies trajectory infeasibility (Theorem N.6).

Why quadratic geometry. Constraint gradients define half-spaces; their intersection is a convex polytope regardless of model nonlinearity. Curvature affects whether the displacement contract holds, not the geometry once it does. Curved paths do not escape the bound (Theorem N.6).

702 **Classical vs. Novel.** The projection geometry and Karush-Kuhn-Tucker (KKT) machinery are
 703 standard [Boyd and Vandenberghe, 2004, Horn and Johnson, 2013]. Our contribution is the *explicit*
 704 *conflict parameterization*: expressing $\|d^*\|$ directly as a function of ρ_{ij} reveals the diagonal cost
 705 structure that classical treatments leave implicit. This parameterization enables the operational
 706 interpretations (staging benefit, feasibility cliff) central to the main text.

707 M.1 Preliminaries and Notation

708 Let $(\mathcal{M}, \langle \cdot, \cdot \rangle)$ be a finite-dimensional real inner product space. At $x \in \mathcal{M}$, associate k differentiable
 709 scalar objectives $L_i : \mathcal{M} \rightarrow \mathbb{R}$ with gradients $g_i = \nabla L_i(x)$ and magnitudes $m_i = \|g_i\|$. We define
 710 first-order feasible displacement $d \in \mathcal{M}$ as satisfying

$$\langle g_i, d \rangle \leq -\tau \quad \text{for all } i. \quad (\text{F})$$

711 where $\tau > 0$ is a fixed local decrease requirement. This standard linearization appears throughout
 712 convex and multiobjective optimization [Fliege and Svaiter, 2000, Boyd and Vandenberghe, 2004].

713 Pairwise conflict is quantified via cosine similarity $c_{ij} := \langle u_i, u_j \rangle \in [-1, 1]$ where $u_i = g_i / \|g_i\|$.
 714 Following Def. 2.6, the *conflict magnitude* is $\rho_{ij} := -c_{ij} \in (0, 1]$ for conflicting constraints ($c_{ij} < 0$).
 715 **Notation:** In derivations below, c denotes cosine similarity. For conflicting constraints, $c = -\rho$
 716 where $\rho > 0$ is the conflict magnitude used in the main text theorems. The Gram matrix $\Gamma \in \mathbb{R}^{k \times k}$
 717 has entries $\Gamma_{ij} = \langle g_i, g_j \rangle = m_i m_j c_{ij}$.

718 **Assumptions.** We explicitly state the minimal assumptions needed for our lower bounds:

- 719 1. **Locality:** First-order approximations hold for $\|d\| \leq \delta$, as in standard analyses of local
 720 descent.
- 721 2. **Smoothness:** $|\langle g_i, d \rangle| \leq m_i \|d\|$ uniformly in the local neighborhood. This matches classical
 722 Lipschitz gradient assumptions [Boyd and Vandenberghe, 2004, Nesterov, 2018].
- 723 3. **Non-degeneracy:** At least one $g_i \neq 0$.

724 **Operational contribution.** While the fundamental objects above are classical, our main paper’s
 725 *diagonal cost interpretation* arises by expressing lower bounds on $\|d\|$ *directly as a function of*
 726 *conflict ρ_{ij} and magnitudes m_i* . This quantifies how constraint coupling amplifies required progress.

727 **Lemma M.2** (First-Order Lower Bound). *For any differentiable function $L : \mathcal{M} \rightarrow \mathbb{R}$ and displace-*
 728 *ment d satisfying $\langle \nabla L(x), d \rangle \leq -\tau$, we have $\|d\| \geq \tau / \|\nabla L(x)\|$.*

729 *Proof.* The descent condition $\langle \nabla L(x), d \rangle \leq -\tau$ implies $|\langle \nabla L(x), d \rangle| \geq \tau$. Applying the Cauchy-
 730 Schwarz inequality yields $|\langle \nabla L(x), d \rangle| \leq \|\nabla L(x)\| \|d\|$. Combining these two bounds gives the
 731 stated result $\|d\| \geq \tau / \|\nabla L(x)\|$. $\square$

732 **Path Integration vs. Displacement Feasibility.** Autoregressive decoding traverses a token path.
 733 Our proofs analyze *displacement feasibility*: existence of a chord Δ from x_0 to a satisfying endpoint
 734 within $B_\delta \cap E(x_0)$. The diagonal cost bound is a *necessary condition* on $\|\Delta\|$; search dynamics are
 735 addressed in Section M.14.

736 M.2 Convex Feasibility and Projection Geometry

737 We review standard results to establish notation consistency. The feasible set $\mathcal{C}$ of first-order satisfying
 738 displacements is

$$\mathcal{C} = \{d \in \mathcal{M} : \langle g_i, d \rangle \leq -\tau \quad \forall i\},$$

739 an intersection of closed half-spaces. As shown in Boyd and Vandenberghe [2004, Sec. 2.2], $\mathcal{C}$ is
 740 nonempty iff feasibility holds.

741 **Lemma M.3** (Projection characterization; classical). *If $\mathcal{C}$ is nonempty, the minimum-norm feasible*
 742 *displacement*

$$d^* = \arg \min_{d \in \mathcal{C}} \|d\|$$

743 *exists and is unique, and is equal to the projection of the origin onto $\mathcal{C}$ [Boyd and Vandenberghe,*
 744 *2004, Thm. 2.1].*

745 This standard observation reduces the lower-bound problem to characterizing the norm of the projected
746 solution.

747 **Lemma M.4** (Minimum-Norm Halfspace Intersection). *Let $\mathcal{H}_1 = \{d : \langle u, d \rangle \leq -\alpha_1\}$ and $\mathcal{H}_2 =$
748 $\{d : \langle v, d \rangle \leq -\alpha_2\}$ where $u, v \in \mathcal{M}$ are unit vectors with cosine $c := \langle u, v \rangle \in (-1, 1)$. The
749 minimum-norm point in $\mathcal{H}_1 \cap \mathcal{H}_2$ is:*

$$d^* = \frac{-\alpha_1 + \alpha_2 c}{1 - c^2} u + \frac{-\alpha_2 + \alpha_1 c}{1 - c^2} v.$$

750 For conflicting constraints ($c < 0$), substituting $c = -\rho$ where $\rho > 0$ is the conflict magnitude yields
751 the main-text formula.

752 *Proof.* The minimum-norm feasibility problem is a convex QP [Boyd and Vandenberghe, 2004,
753 Chap. 4]. The Lagrangian is:

$$\mathcal{L}(d, \lambda_1, \lambda_2) = \frac{1}{2} \|d\|^2 + \lambda_1 (\langle u, d \rangle + \alpha_1) + \lambda_2 (\langle v, d \rangle + \alpha_2).$$

754 Setting $\nabla_d \mathcal{L} = 0$: $d = -\lambda_1 u - \lambda_2 v$.

755 By complementary slackness [Boyd and Vandenberghe, 2004, Sec. 5.5.2], both constraints are active
756 at optimum:

$$\begin{aligned} -\lambda_1 - \lambda_2 c &= -\alpha_1 \\ -\lambda_1 c - \lambda_2 &= -\alpha_2 \end{aligned}$$

757 The system has determinant $1 - c^2 > 0$ for $|c| < 1$. Solving via Cramer's rule yields the stated
758 form. $\square$

759 M.3 Two-Constraint Lower Bound (Theorem 3.3)

760 The following theorem corresponds to Theorem 3.3 in the main text, now presented with its complete
761 derivation. Recall: c denotes cosine similarity, and for conflicting constraints, $c = -\rho$ where $\rho > 0$
762 is the conflict magnitude.

763 **Theorem M.5** (Two-constraint lower bound; explicit conflict instantiation). *Let $g_1, g_2 \in \mathcal{M}$ be
764 nonzero gradients with magnitudes m_1, m_2 and conflict magnitude $\rho > 0$ (cosine $c = -\rho$). Assume
765 feasibility holds. Then every d satisfying (F) obeys*

$$\|d\| \geq \frac{\tau \sqrt{2}}{\sqrt{m_1^2 + m_2^2 - 2\rho m_1 m_2}}.$$

766 **Classical structure.** The derivation utilizes the standard identity $\|d\|^2 = \tau^2 \mathbf{1}^\top \Gamma^{-1} \mathbf{1}$ for active
767 constraints [Boyd and Vandenberghe, 2004, cf. pp. 231–233], combined with basic properties of
768 Gram matrices [Horn and Johnson, 2013].

769 *Proof.* Let $u_i = g_i/m_i$ be unit gradient directions with cosine $c = \langle u_1, u_2 \rangle = -\rho$. At the minimum-
770 norm solution, both constraints are active (by convexity; see Boyd and Vandenberghe 2004, Sec. 3.2),
771 so we solve the KKT system. By Lemma M.4 with $\alpha_i = \tau/m_i$:

$$d^* = \gamma_1 u_1 + \gamma_2 u_2, \quad \gamma_i = \frac{-\alpha_i + \alpha_j c}{1 - c^2}.$$

772 The Gram matrix of unit gradients is $G = \begin{pmatrix} 1 & c \\ c & 1 \end{pmatrix}$ with $G^{-1} = \frac{1}{1-c^2} \begin{pmatrix} 1 & -c \\ -c & 1 \end{pmatrix}$.

773 Computing $\|d^*\|^2 = \gamma_1^2 + \gamma_2^2 + 2\gamma_1\gamma_2 c$ and simplifying:

$$\|d^*\|^2 = \frac{\alpha_1^2 + \alpha_2^2 - 2c\alpha_1\alpha_2}{1 - c^2}.$$

774 For the uniform case $\alpha_1 = \alpha_2 = \tau/m$, substituting $c = -\rho$:

$$\|d^*\|^2 = \frac{2(\tau/m)^2(1 + \rho)}{1 - \rho^2} = \frac{2\tau^2}{m^2(1 - \rho)}.$$

775 Taking square roots yields the main-text formula:

$$\|d^*\| = \frac{\tau}{m} \sqrt{\frac{2}{1 - \rho}}. \quad \square$$

776 **Operational interpretation (our contribution).** While the above steps are classical, expressing
 777 the denominator directly in terms of ρ and m_i makes the *amplification of feasible progress cost under*
 778 *conflict* explicit, establishing the diagonal cost phenomenon central to the main paper.

779 M.4 k-Constraint Lower Bound (Theorem 3.6)

780 **Theorem M.6** (k -constraint lower bound; Gram-spectrum formulation). *Let $G \in \mathbb{R}^{k \times \dim(\mathcal{M})}$ collect*
 781 *unit gradients row-wise, and $\Gamma = GG^\top$ be the Gram matrix. Assume Γ is positive definite. Then*
 782 *every d satisfying (F) obeys*

$$\|d\| \geq \frac{\tau}{m} \sqrt{\mathbf{1}^\top \Gamma^{-1} \mathbf{1}} \geq \frac{\tau}{m} \sqrt{\frac{k}{1 - \rho(k-1)}}, \quad (\text{A1})$$

783 where the second inequality assumes uniform pairwise conflict $\rho_{ij} \leq -\rho$ for all $i \neq j$.

784 *Proof.* The projection argument follows Lemma M.3, yielding the minimum-norm feasibility prob-
 785 lem:

$$\min_d \frac{1}{2} \|d\|^2 \quad \text{s.t.} \quad \langle u_i, d \rangle \leq -\alpha \quad \forall i,$$

786 where $\alpha = \tau/m$ and u_i are unit gradient directions.

787 At optimality, by KKT conditions, $d^* = -\sum_i \lambda_i u_i$ where $\lambda \geq 0$. For symmetric constraints with
 788 uniform α , symmetry implies $\lambda_i = t$ for all i . Then $Gd^* = -t\Gamma\mathbf{1} = -\alpha\mathbf{1}$, so $d^* = -\alpha G^\dagger \mathbf{1} =$
 789 $-\alpha G^\top (GG^\top)^{-1} \mathbf{1}$ [Horn and Johnson, 2013, Chap. 6].

790 Computing the norm:

$$\|d^*\|^2 = \alpha^2 \mathbf{1}^\top \Gamma^{-1} \Gamma \Gamma^{-1} \mathbf{1} = \alpha^2 \mathbf{1}^\top \Gamma^{-1} \mathbf{1}.$$

791 For the uniform conflict bound, when $\langle u_i, u_j \rangle = -\rho$ for all $i \neq j$:

$$\Gamma = (1 + \rho)I - \rho \mathbf{1}\mathbf{1}^\top.$$

792 By the Sherman-Morrison formula [Horn and Johnson, 2013]:

$$\Gamma^{-1} = \frac{1}{1 + \rho} \left(I + \frac{\rho}{1 - \rho(k-1)} \mathbf{1}\mathbf{1}^\top \right).$$

793 Thus $\mathbf{1}^\top \Gamma^{-1} \mathbf{1} = \frac{k}{1 - \rho(k-1)}$, yielding the stated bound. **Symbolic verification:** SymPy derivation
 794 confirms this formula exactly for $k \in \{2, 3, 4, 5\}$ with phase transition at $\rho = 1/(k-1)$. Code:
 795 `supplementary/bridges/gram_matrix_verification.py`. $\square$

796 **Operational contribution.** While (A1) is structurally classical, our main paper uses this expression
 797 to quantify *how conflict structure (via the Gram spectrum) governs observable failure thresholds* in
 798 multi-constraint satisfaction.

799 M.5 Staging Benefit Analysis

800 We now prove that staged satisfaction reduces required step magnitude when constraints are resolved
 801 sequentially.

802 **Why staging escapes implicit- k .** One-shot generation must respect all k constraint gradients
 803 simultaneously: the full Gram matrix Γ must be “held in budget.” When implicit constraints
 804 (grammar, coherence) inflate k , the diagonal cost bound becomes restrictive. Staging escapes this:
 805 each step resolves one constraint, requiring only one gradient at a time. The model never needs to
 806 compute or budget for the global geometry. It iteratively constructs a solution where step $t+1$ takes
 807 x_t as a fixed anchor. This is why staging circumvents the “implicit k is unknowable” objection: the
 808 bound applies to simultaneous satisfaction, not sequential.

809 **Proposition M.7** (Staging reduces diagonal cost). *Let k constraints have pairwise conflict $\rho_{ij} = -\rho$*
 810 *for all $i \neq j$. Sequential satisfaction with perfect preservation requires per-step magnitude $\delta_{\text{staged}} =$*
 811 *τ/m , while simultaneous satisfaction requires $\delta_{\text{sim}} \geq (\tau/m) \sqrt{k/(1 - \rho(k-1))}$.*

812 The staging benefit ratio is:

$$\frac{\delta_{sim}}{\delta_{staged}} = \sqrt{\frac{k}{1 - \rho(k-1)}} \xrightarrow{\rho \rightarrow 1/(k-1)} \infty.$$

813 *Proof.* For single-constraint satisfaction, the minimum progress is $\|d\| \geq \tau/m$ by Cauchy-Schwarz
 814 (Lemma M.2 in the original).

815 If staged satisfaction perfectly preserves prior constraints (i.e., moves orthogonally to previously
 816 satisfied gradient directions), each stage faces only one active constraint with descent requirement τ .

817 For simultaneous satisfaction, Theorem M.6 gives the stated bound.

818 The ratio follows by division. As $\rho \rightarrow 1/(k-1)$, the denominator $1 - \rho(k-1) \rightarrow 0$, making
 819 simultaneous satisfaction require arbitrarily large steps. $\square$

820 **Connection to Constitutional AI.** This proposition formalizes why critique-revision loops (Consti-
 821 tutional AI’s core mechanism) succeed: each revision targets one principle at a time, avoiding the
 822 diagonal cost amplification that would arise from simultaneous multi-principle optimization.

823 M.6 High- ρ Bounds and Degeneracy

824 When $\rho \geq 1/(k-1)$, the Gram matrix Γ becomes singular or indefinite. We characterize the resulting
 825 behavior.

826 **Proposition M.8** (Gram matrix spectrum). *For k constraints with uniform pairwise conflict $\rho_{ij} = -\rho$,
 827 the Gram matrix $\Gamma = (1 + \rho)I - \rho\mathbf{1}\mathbf{1}^\top$ has eigenvalues:*

- 828 • $\lambda_1 = 1 - \rho(k-1)$ with eigenvector $\mathbf{1}$
- 829 • $\lambda_{2,\dots,k} = 1 + \rho$ with multiplicity $k-1$

830 Γ is positive definite iff $\rho < 1/(k-1)$.

831 *Proof.* Direct computation. $\Gamma\mathbf{1} = (1 + \rho)\mathbf{1} - k\rho\mathbf{1} = (1 - \rho(k-1))\mathbf{1}$. For $v \perp \mathbf{1}$: $\Gamma v = (1 + \rho)v$.
 832 Positive definiteness requires all eigenvalues positive: $1 - \rho(k-1) > 0 \Leftrightarrow \rho < 1/(k-1)$. $\square$

833 At $\rho = 1/(k-1)$, the constraint gradients become coplanar (linearly dependent), and the feasible
 834 region $\mathcal{C}$ degenerates: the analog of Slater’s condition failure in convex optimization (no strictly
 835 feasible interior point). For $\rho > 1/(k-1)$, the gradients point “more than orthogonally” apart,
 836 creating an infeasible configuration where no direction simultaneously decreases all objectives.

837 **Fragmentation regime.** Our IF-DSL experiments (Appendix R) empirically confirm this analysis:
 838 at $\rho = 1.0$ (maximally conflicting constraints like `one_bottleneck + pathlen_eq_5`), pass rates
 839 collapse to 0% regardless of budget or protocol. The geometric prediction matches observed behavior.

840 M.7 Tightness of Bounds

841 **Proposition M.9** (Tightness). *The bounds in Theorems M.5 and M.6 are tight: there exist constraint
 842 configurations achieving equality.*

843 *Proof.* The minimum-norm solution d^* achieving the bound exists by construction. The bound is
 844 achieved when:

- 845 1. All constraints are active at d^* (no slack)
- 846 2. The constraint normals span the subspace containing d^*

847 For $k = 2$ with $\rho \in (-1, 1)$, both conditions hold generically. For general k , tightness holds when
 848 the Gram matrix is positive definite and the problem is strictly feasible [Boyd and Vandenberghe,
 849 2004, Thm. 5.2.1].

850 As Table A11 demonstrates, synthetic optimization matches analytical bounds to relative error $< 10^{-8}$
 851 across all tested configurations. $\square$

852 **Necessity of Conflict Structure (Information-Theoretic).** The parameter ρ enters necessarily:
 853 setting $\rho = 0$ (orthogonal constraints) collapses the bound to $\|d^*\| = \tau\sqrt{k}/m$, the axis-aligned
 854 case where no amplification occurs. The $1/(1 - \rho)$ factor captures exactly the geometric cost of
 855 non-orthogonality: an information-theoretic lower bound, not a modeling choice.

856 **Robustness Under Mild Curvature.** The first-order analysis assumes locally linear constraint
 857 surfaces. Under bounded curvature $\|\nabla^2 L_i\| \leq \kappa$, the projection-based lower bound persists up to
 858 $O(\kappa\|d\|^2)$ corrections. Specifically, for $\|d\| \ll 1/\kappa$, the diagonal cost regime is not an artifact of
 859 strict linearity. It reflects genuine geometric structure that curvature perturbs but does not eliminate.

860 M.8 Connection to Pareto Optimality

861 We establish the relationship between our lower bounds and classical Pareto theory [Ehrgott, 2005].

862 **Definition M.10** (Pareto efficiency). A point $x \in \mathcal{M}$ is *Pareto efficient* for objectives $\{L_i\}_{i=1}^k$ if
 863 there exists no x' with $L_i(x') \leq L_i(x)$ for all i and strict inequality for some i .

864 **Proposition M.11** (Diagonal cost at Pareto points). *At a Pareto efficient point x^* , the minimum-norm
 865 direction achieving simultaneous first-order decrease on all objectives has norm*

$$\|d^*\| = \tau\sqrt{\mathbf{1}^\top \Gamma^{-1} \mathbf{1}},$$

866 where Γ is the Gram matrix of gradients at x^* . The Pareto front curvature is governed by $\rho_{\max} =$
 867 $\max_{i \neq j} \rho_{ij}$.

868 *Proof.* At Pareto efficiency, all constraints are active: any slack would permit Pareto improvement.
 869 Thus the minimum-norm solution lies at the intersection of all constraint hyperplanes, giving $\|d^*\|^2 =$
 870 $\tau^2 \mathbf{1}^\top \Gamma^{-1} \mathbf{1}$ by the derivation in Theorem M.6.

871 The Pareto front curvature relates to $\rho_{\max}$ because high conflict between gradients implies sharp
 872 trade-offs: moving toward one objective moves sharply away from another, creating a highly curved
 873 front [Deb et al., 2002]. $\square$

874 **Corollary M.12** (Pareto navigation cost). *Moving along the Pareto front by ϵ in objective i while
 875 maintaining Pareto efficiency requires displacement magnitude $\Omega(\epsilon/\sqrt{1 - \rho_{\max}})$ when $\rho_{\max}$ is close
 876 to the critical threshold.*

877 *Proof.* Pareto navigation requires maintaining first-order decrease on all objectives except i . This
 878 is a $(k - 1)$ -constraint problem with the same conflict structure. By Theorem M.6, the minimum
 879 displacement scales as $\sqrt{(k - 1)/(1 - \rho_{\max}(k - 2))} = \Omega(1/\sqrt{1 - \rho_{\max}})$ near criticality. $\square$

880 M.9 Heterogeneous Magnitudes: Complete Treatment

881 We extend the uniform-magnitude results to the general case where $m_i = \|g_i\|$ may differ across
 882 constraints.

883 **Theorem M.13** (Heterogeneous diagonal cost). *For k constraints with gradient magnitudes $\{m_i\}_{i=1}^k$
 884 and pairwise conflicts $\{\rho_{ij}\}_{i < j}$, define the normalized Gram matrix $\tilde{\Gamma}$ with entries $\tilde{\Gamma}_{ij} = \rho_{ij}$ for
 885 $i \neq j$ and $\tilde{\Gamma}_{ii} = 1$. Let $M = \text{diag}(m_1, \dots, m_k)$. Then:*

$$\|d^*\|^2 = \tau^2 \mathbf{1}^\top (M \tilde{\Gamma} M)^{-1} \mathbf{1} = \tau^2 \mathbf{1}^\top M^{-1} \tilde{\Gamma}^{-1} M^{-1} \mathbf{1}.$$

886 *Proof.* The Gram matrix of unnormalized gradients is $\Gamma = M \tilde{\Gamma} M$ where $\tilde{\Gamma}$ contains the correlation
 887 structure. The minimum-norm solution satisfies $\|d^*\|^2 = \tau^2 \mathbf{1}^\top \Gamma^{-1} \mathbf{1}$. Substituting and using
 888 $(ABC)^{-1} = C^{-1} B^{-1} A^{-1}$ yields the result. $\square$

889 **Corollary M.14** (Magnitude-conflict interaction). *When constraints have heterogeneous magnitudes,*
 890 *the effective diagonal cost depends on both conflict structure and magnitude ratios. Specifically, for*
 891 *$k = 2$:*

$$\|d^*\| = \tau \sqrt{\frac{1/m_1^2 + 1/m_2^2 - 2\rho/(m_1 m_2)}{1 - \rho^2}}.$$

892 *Large-magnitude constraints (high m_i) contribute less to the diagonal cost per unit of required*
 893 *decrease.*

894 *Proof.* For $k = 2$, $M^{-1} = \text{diag}(1/m_1, 1/m_2)$ and $\tilde{\Gamma}^{-1} = \frac{1}{1-\rho^2} \begin{pmatrix} 1 & -\rho \\ -\rho & 1 \end{pmatrix}$. Computing
 895 $\mathbf{1}^\top M^{-1} \tilde{\Gamma}^{-1} M^{-1} \mathbf{1}$ and simplifying yields the stated formula. $\square$

896 M.10 Iterative Satisfaction: Convergence Analysis

897 We analyze convergence rates for iterative methods that approximate staged satisfaction. The iterative
 898 protocol defined in Section J.14 is a behavioral instantiation of the Kaczmarz method [Kaczmarz,
 899 1937], also known in the optimization literature as the Method of Cyclic Projections [Gubin et al.,
 900 1967]. Theorem J.15 inherits the classical linear convergence rates of these methods, adapted to the
 901 local linearized geometry of the embedding manifold.

902 **Definition M.15** (Projected gradient iteration). Given current point x_t and constraint i_t (selected
 903 cyclically or by rule), the projected gradient step is:

$$x_{t+1} = x_t - \eta_t \frac{\langle g_{i_t}, x_t - x_{i_t}^* \rangle}{\|g_{i_t}\|^2} g_{i_t},$$

904 where $x_{i_t}^*$ is the projection onto constraint i_t 's satisfying halfspace.

905 **Theorem M.16** (Cyclic projection convergence). *For k constraints with pairwise conflicts $\rho_{ij} \leq$*
 906 *$\rho_{\max} < 1$, cyclic projected gradient iteration converges linearly:*

$$\|x_T - x^*\| \leq \left(1 - \frac{1 - \rho_{\max}}{k}\right)^{T/k} \|x_0 - x^*\|.$$

907 *The convergence rate degrades as $\rho_{\max} \rightarrow 1$.*

908 *Proof sketch.* Each projection onto constraint i 's halfspace reduces squared distance to the feasible
 909 region by factor $(1 - c_i)$ where c_i depends on the angle between g_i and the current residual. For
 910 non-degenerate configurations with $\rho_{\max} < 1$, the constraints are linearly independent, ensuring
 911 $c_i \geq (1 - \rho_{\max})/k$ on average over a full cycle [cf. Bauschke and Borwein, 1996, Thm. 4.1]. The
 912 product of k such contractions over one cycle yields the stated bound. $\square$

913 **Corollary M.17** (Iteration complexity). *For ϵ -feasibility, iteration count scales as $T = O(k \cdot (1 -$
 914 $\rho_{\max})^{-1} \cdot \log(1/\epsilon))$, consistent with the $1/(1 - \rho)$ factor in the diagonal cost bound.*

915 *Proof.* By Theorem M.16, after T iterations, $\|x_T - x^*\| \leq (1 - (1 - \rho_{\max})/k)^{T/k} \|x_0 - x^*\|$. Setting
 916 this equal to ϵ and solving: $T/k \cdot \log(1 - (1 - \rho_{\max})/k) \leq \log(\epsilon/\|x_0 - x^*\|)$. Using $\log(1 - x) \approx -x$
 917 for small x , we get $T \geq \frac{k^2}{1 - \rho_{\max}} \log(1/\epsilon)$, which simplifies to the stated $O(k/(1 - \rho_{\max}) \log(1/\epsilon))$
 918 when accounting for per-cycle progress. $\square$

919 M.11 Perturbation Analysis and Robustness

920 We establish stability of the diagonal cost under perturbations to the constraint gradients.

921 **Theorem M.18** (Perturbation bound). *Let $\{g_i\}$ be the original gradients with Gram matrix Γ , and*
 922 *let $\{\tilde{g}_i\}$ be perturbed gradients with $\|g_i - \tilde{g}_i\| \leq \epsilon m_i$. Let $\tilde{\Gamma}$ be the perturbed Gram matrix. Then:*

$$\left| \sqrt{\mathbf{1}^\top \Gamma^{-1} \mathbf{1}} - \sqrt{\mathbf{1}^\top \tilde{\Gamma}^{-1} \mathbf{1}} \right| \leq O\left(\frac{k\epsilon}{\lambda_{\min}(\Gamma)}\right) \sqrt{\mathbf{1}^\top \Gamma^{-1} \mathbf{1}},$$

923 *where $\lambda_{\min}(\Gamma) = 1 - \rho_{\max}(k - 1)$ for uniform conflict.*

924 *Proof.* By standard matrix perturbation theory [Horn and Johnson, 2013, Thm. 2.8], for symmetric
 925 positive definite Γ and perturbation $\Delta\Gamma$ with $\|\Delta\Gamma\| \leq \delta$:

$$\|\Gamma^{-1} - (\Gamma + \Delta\Gamma)^{-1}\| \leq \frac{\delta}{\lambda_{\min}(\Gamma)(\lambda_{\min}(\Gamma) - \delta)}.$$

926 The perturbation $\|\Delta\Gamma\| = O(k\epsilon \max_i m_i^2)$ since each entry of Γ changes by at most $O(\epsilon m_i m_j)$.
 927 Applying to the quadratic form $\mathbf{1}^\top \Gamma^{-1} \mathbf{1}$ and taking square roots yields the bound. $\square$

928 **Corollary M.19** (Robustness near criticality). *As $\rho \rightarrow 1/(k-1)$, $\lambda_{\min}(\Gamma) \rightarrow 0$, and the diagonal
 929 cost becomes increasingly sensitive to perturbations. This explains empirical observations that
 930 high-conflict configurations exhibit unstable behavior: small changes in constraint specification can
 931 dramatically alter feasibility.*

932 *Proof.* From Theorem M.18, the relative perturbation in diagonal cost is $O(k\epsilon/\lambda_{\min}(\Gamma))$. By
 933 Proposition M.8, $\lambda_{\min}(\Gamma) = 1 - \rho(k-1)$ for uniform conflict. As $\rho \rightarrow 1/(k-1)$, $\lambda_{\min} \rightarrow 0$,
 934 causing the perturbation bound to diverge. This formalizes the instability observed in high-conflict
 935 regimes. $\square$

936 M.12 Algorithmic Implications

937 Our bounds have direct implications for algorithm design in multi-constraint optimization.

938 **Proposition M.20** (Optimal constraint ordering for staging). *For staged satisfaction of k constraints,
 939 the optimal ordering minimizes total path length. Given conflict matrix P with $P_{ij} = \rho_{ij}$, the optimal
 940 ordering π satisfies:*

$$\pi^* = \arg \min_{\pi} \sum_{t=1}^{k-1} \sqrt{1 + 2 \sum_{s < t} \rho_{\pi(s)\pi(t)}}.$$

941 *For $k = 2$: satisfy the higher-magnitude constraint first.*

942 *Proof.* At each stage t , we satisfy constraint $\pi(t)$ while preserving $\{\pi(1), \dots, \pi(t-1)\}$. The
 943 preservation requirement adds effective conflict from previously satisfied constraints. The minimum-
 944 norm step at stage t has magnitude determined by the effective Gram matrix of $\{g_{\pi(1)}, \dots, g_{\pi(t)}\}$.
 945 Summing over stages and minimizing over orderings yields the optimization problem.

946 For $k = 2$: satisfying the larger-magnitude constraint first means subsequent preservation is easier
 947 (moving in the high- m direction requires less displacement per unit of τ). $\square$

948 **Remark M.21** (Comparison to gradient conflict methods). Our ordering criterion differs from PCGrad
 949 [Yu et al., 2020] and CAGrad [Liu et al., 2021], which project conflicting gradients during *training*
 950 (weight updates). Our analysis operates at *inference time* on a frozen model, controlling generation
 951 trajectory rather than training dynamics. Both address the same conflict geometry ($\rho_{ij} < 0$), but at
 952 different stages: they reduce conflict during parameter optimization; we detect and route around it
 953 during output optimization.

954 M.13 Extension to Inequality Constraints

955 The main results extend to mixed equality/inequality constraint settings.

956 **Proposition M.22** (Active set characterization). *Consider k inequality constraints $\langle g_i, d \rangle \leq -\tau_i$
 957 where some may be inactive at the optimum. Let $\mathcal{A} \subseteq \{1, \dots, k\}$ denote the active set. Then:*

$$\|d^*\|^2 = \tau_{\mathcal{A}}^\top \Gamma_{\mathcal{A}}^{-1} \tau_{\mathcal{A}},$$

958 where $\Gamma_{\mathcal{A}}$ is the Gram matrix restricted to active constraints and $\tau_{\mathcal{A}}$ is the corresponding vector of
 959 thresholds.

960 *Proof.* By KKT conditions, inactive constraints have zero multipliers and don't affect the optimal
 961 solution. The active constraints form an equality system, reducing to the previous analysis. $\square$

Corollary M.23 (Diagonal cost is determined by hardest subset). *The diagonal cost is determined by the maximally conflicting active subset. Adding easy (orthogonal) constraints doesn't increase the bound, but adding conflicting constraints may activate new constraints and increase the cost.*

Proof. By Proposition M.22, only active constraints contribute to $\|d^*\|$. If a new constraint j is orthogonal to all active constraints ($\rho_{ij} = 0$ for $i \in \mathcal{A}$), the augmented Gram matrix is block-diagonal and $\|d^*\|$ depends only on $\Gamma_{\mathcal{A}}$. If j conflicts with active constraints, it may become active, enlarging $\mathcal{A}$ and potentially increasing the diagonal cost via the $\mathbf{1}^\top \Gamma^{-1} \mathbf{1}$ term. $\square$

M.14 Global Extension

The bounds established above are local, holding within neighborhoods where first-order approximations apply. We now show they integrate to a global constraint.

Theorem M.24 (Global Diagonal Cost). *Let $\gamma : [0, 1] \rightarrow \mathcal{M}$ be any trajectory achieving τ -progress on all k constraints, i.e., $r_i(\gamma(1)) \leq r_i(\gamma(0)) - \tau$ for all i . Under bounded curvature ($\|\nabla^2 r_i\| \leq \kappa$ everywhere), the arc length satisfies:*

$$\int_0^1 \|\dot{\gamma}(t)\| dt \geq \frac{\tau}{m} \sqrt{\frac{k}{1 - \bar{\rho}(k-1)}} - O(\kappa\tau),$$

where $\bar{\rho} := \frac{1}{\tau} \int_0^1 \rho(\gamma(t)) \|\dot{\gamma}(t)\| dt$ is the path-averaged conflict and $m = \min_i \|\nabla r_i\|$.

Proof. Partition $[0, 1]$ into N segments $[t_j, t_{j+1}]$ with $\|\gamma(t_{j+1}) - \gamma(t_j)\| = \epsilon := L/N$ where L is total arc length. On each segment:

Step 1 (Local bound applies): By Lemma N.4, the residual satisfies $r_i(\gamma(t_{j+1})) = r_i(\gamma(t_j)) + \langle \nabla r_i(\gamma(t_j)), \Delta_j \rangle + O(\kappa\epsilon^2)$ where $\Delta_j = \gamma(t_{j+1}) - \gamma(t_j)$. For τ_j -progress on segment j , the local bound (Theorem 3.6) requires:

$$\|\Delta_j\| \geq \frac{\tau_j}{m_j} \sqrt{\frac{k}{1 - \rho_j(k-1)}} - O(\kappa\epsilon^2/\tau_j),$$

where $\rho_j = \rho(\gamma(t_j))$ and $m_j = \min_i \|\nabla r_i(\gamma(t_j))\|$.

Step 2 (Sum over segments): Total progress $\tau = \sum_j \tau_j$. Summing the local bounds:

$$L = \sum_j \|\Delta_j\| \geq \sum_j \frac{\tau_j}{m_j} \sqrt{\frac{k}{1 - \rho_j(k-1)}} - O(N\kappa\epsilon^2/\bar{\tau}).$$

The correction term is $O(N\kappa(L/N)^2) = O(\kappa L^2/N) \rightarrow 0$ as $N \rightarrow \infty$.

Step 3 (Limit): Taking $N \rightarrow \infty$, the Riemann sum converges:

$$L \geq \int_0^1 \frac{1}{m(\gamma(t))} \sqrt{\frac{k}{1 - \rho(\gamma(t))(k-1)}} d\tau(t),$$

where $d\tau(t)$ is the progress measure. By Jensen's inequality on the convex function $f(\rho) = \sqrt{k/(1 - \rho(k-1))}$ and using $m \geq m_{\min}$:

$$L \geq \frac{\tau}{m} \sqrt{\frac{k}{1 - \bar{\rho}(k-1)}} - O(\kappa\tau),$$

where the $O(\kappa\tau)$ absorbs the curvature corrections accumulated along the path. $\square$

Corollary M.25 (Curvature cannot defeat the bound). *The global bound has the same $\sqrt{k/(1 - \rho(k-1))}$ scaling as the local bound. Curvature contributes only an additive $O(\kappa\tau)$ correction, not a multiplicative escape. For typical values ($\kappa\tau \ll 1$), the local and global bounds coincide.*

This theorem closes the “local vs. global” gap: the diagonal cost is not merely a local phenomenon but a geometric invariant of any trajectory achieving multi-constraint progress.

994 **M.15 Rank-Deficiency Boundary (relocated from body)**

995 Figure A1 shows cost divergence as conflict approaches the singularity.

Figure A1: **Cost Amplification.** The diagonal cost factor $\sqrt{2/(1-\rho)}$ diverges as conflict $\rho \rightarrow 1$. At $\rho = 0$ (orthogonal), cost is $\sqrt{2} \approx 1.41$; at $\rho = 0.5$, cost doubles; at $\rho = 0.9$, cost exceeds $4\times$.

996 Figure A1 shows amplification diverges as $\rho \rightarrow 1$: $1.4\text{--}2\times$ for $\rho < 0.5$; diverges for $\rho \geq 0.8$. IF-DSL
 997 confirms: $\rho = 1.0 \Rightarrow 0\%$ pass regardless of budget.

998 **Proposition M.26** (Critical Threshold). $\rho_c = 1 - 2\tau^2/(m^2\delta^2)$. For $\rho > \rho_c$: *infeasible*; see
 999 Appendix M.

1000 Proposition M.26 yields: for $\delta/\delta_{\min} \approx 1.1$, $\rho_c \approx 0.30$. Systems near Pareto boundary experience
 1001 cascading failures from small ρ increases. Table A19 shows protocol comparison at high $\hat{\rho}$.

1002 **Novelty:** Bound is classical MOO; contribution is gradient-free operationalization. **Disambiguation:**
 1003 $\hat{\rho}$ triggers routing; domain checks resolve hard-negatives (Appendix O.3).

Table A19: Protocol comparison (High- $\hat{\rho}$). Router matches staged pass rate, 25% fewer tokens.

Protocol	Pass%	Tokens	vs. Oracle
One-shot	5%	256	−16%
Best-of-4	12%	1024	−9%
Self-refine	15%	640	−6%
Geometric router	18%	384	−3%

1004 **N Budgeted Local Linearity and Staging as Path Parameterization**

1005 This appendix formalizes the relationship between operational budgets, local linearity, and staged
 1006 decomposition. We show that (i) local linearity is an *operational consequence* of small-step budgeting,
 1007 not a global flatness assumption, and (ii) staging is an explicit reparameterization of total budget into
 1008 a piecewise-linear path.

1009 **N.1 Trajectories, Budget, and Utilized Budget**

1010 Let x_t denote the model’s state after emitting t tokens, and let $\Phi(x)$ denote the chosen representation
 1011 (e.g., encoder embedding). We study the induced trajectory $z_t := \Phi(x_t) \in \mathbb{R}^d$.

1012 **Definition N.1** (Per-step and utilized budget). A generation induces increments $\Delta z_t := z_{t+1} - z_t$.
 1013 The *utilized budget* over T steps is $B_T := \sum_{t=0}^{T-1} \|\Delta z_t\|$. We say the generator satisfies a *per-step*
 1014 budget L if $\|\Delta z_t\| \leq L$ for all t , and a *total budget* B if $B_T \leq B$.

1015 **Lemma N.2** (Token budget induces norm-budget ball). If $\|\Delta z_t\| \leq L$ for all t , then $\|z_T - z_0\| \leq$
 1016 $\sum_{t=0}^{T-1} \|\Delta z_t\| \leq LT$. Thus any length- T response remains within radius LT of z_0 .

1017 *Proof.* Triangle inequality: $\|z_T - z_0\| = \|\sum_{t=0}^{T-1} \Delta z_t\| \leq \sum_{t=0}^{T-1} \|\Delta z_t\| \leq LT$. $\square$

1018 **Remark (repetition does not break the contract).** A model may emit tokens with little semantic
 1019 movement (near-zero $\|\Delta z_t\|$), which only *reduces* B_T (Definition N.1). Lemma N.2 then gives a
 1020 tighter ball. Conversely, the contract is refutable: frequent large $\|\Delta z_t\|$ spikes require recalibrating L
 1021 or rejecting Φ .

1022 N.2 Bounded Curvature and Local Linearity

1023 Let constraints be encoded as residuals $r_i : \mathbb{R}^d \rightarrow \mathbb{R}$, where $r_i(z) \leq 0$ means constraint i is satisfied.

1024 **Assumption N.3** (Bounded curvature). Each r_i has K_i -Lipschitz gradient: $\|\nabla r_i(z + \Delta) - \nabla r_i(z)\| \leq$
 1025 $K_i \|\Delta\|$. Let $K := \max_i K_i$.

1026 **Lemma N.4** (Local linearity from small steps). *Under Assumption N.3, $r_i(z + \Delta) \leq r_i(z) +$
 1027 $\langle \nabla r_i(z), \Delta \rangle + \frac{K}{2} \|\Delta\|^2$. On steps with $\|\Delta\| \leq \varepsilon$, deviation from linear prediction is $O(\varepsilon^2)$.*

1028 *Proof.* Taylor expansion with Lipschitz gradient: $|r_i(z + \Delta) - r_i(z) - \langle \nabla r_i(z), \Delta \rangle| \leq (K/2) \|\Delta\|^2$
 1029 (standard; see Nesterov [2018]). $\square$

1030 **Interpretation.** Local linearity is not a global flatness claim. Once budget enforces small steps,
 1031 first-order geometry controls feasibility up to a quadratic remainder. Budget $\Rightarrow$ local linearity.

1032 N.3 One-Shot Diagonal Cost vs Staged Parameterization

1033 At anchor z , define $g_i := \nabla r_i(z)$. In the linear model, simultaneous τ -progress requires $\langle g_i, \Delta \rangle \leq -\tau$
 1034 for all active i , yielding the diagonal cost bound $\delta_{\min}$.

1035 A *staged* policy is a sequence $\pi = (i_1, \dots, i_S)$ with anchors: $z^{(0)} = z$, $z^{(s+1)} = z^{(s)} + \Delta^{(s)}$, where
 1036 stage s prioritizes constraint i_{s+1} with per-stage budget $\|\Delta^{(s)}\| \leq \delta_s$.

1037 **Proposition N.5** (Staging as polygonal path). *Any staged policy satisfies $\|z^{(S)} - z^{(0)}\| \leq \sum_{s=0}^{S-1} \delta_s$.
 1038 Staging parameterizes total budget into a piecewise-linear path whose segments align to constraint
 1039 directions per precedence π .*

1040 *Proof.* Triangle inequality on the polygonal chain: $\|z^{(S)} - z^{(0)}\| = \|\sum_{s=0}^{S-1} \Delta^{(s)}\| \leq$
 1041 $\sum_{s=0}^{S-1} \|\Delta^{(s)}\| \leq \sum_s \delta_s$. $\square$

1042 **Defeating “flatness bias.”** The one-shot bound concerns the single-segment chord. Proposition N.5
 1043 shows staging replaces it by a polygonal chain tracking changing tangents $g_i(z^{(s)})$. Under Assump-
 1044 tion N.3 and small δ_s , each segment remains in a regime where Lemma N.4 validates the linear
 1045 model. We do not change the topology of $\mathbb{R}^d$. Staging enlarges the *decision variable* from a single
 1046 chord Δ to a path (polygonal chain) with intermediate anchors, enabling re-linearization under the
 1047 same budget contract. Residual coupling across stages is captured by preservation/regression costs
 1048 (Appendix L), which is why staging helps only in an intermediate conflict band. It is not a universal
 1049 solution.

1050 N.4 Curvature Cannot Remove the Boundary at Small Budgets

1051 **Theorem N.6** (Budgeted infeasibility persists). *Fix anchor z and required progress τ . Suppose the
 1052 linear problem requires $\|\Delta\| \geq \delta_{\min}$. Under Assumption N.3, any Δ with $\|\Delta\| \leq \delta$ can achieve
 1053 simultaneous progress only if $\delta \geq \delta_{\min} - O(K\delta^2/\tau)$. Curvature changes feasibility only through a
 1054 quadratic correction at the budget scale.*

1055 *Proof.* By Lemma N.4, $r_i(z + \Delta) \leq r_i(z) + \langle \nabla r_i(z), \Delta \rangle + (K/2) \|\Delta\|^2$. Requiring $r_i(z + \Delta) \leq$
 1056 $r_i(z) - \tau$ implies $\langle \nabla r_i(z), \Delta \rangle \leq -\tau + (K/2) \|\Delta\|^2$. The linear bound $\delta_{\min}$ is relaxed by at most
 1057 $(K/2)\delta^2/\tau$ when $\|\Delta\| \leq \delta$. $\square$

1058 **Consequence (sharp cliffs).** If failure exhibits sharp transitions as budget crosses predicted thresh-
 1059 olds, this is consistent with Theorem N.6: first-order geometry controls, curvature enters only at
 1060 second order.

1061 **Corollary N.7** (Escaping the bound requires a regime break). *If $\delta_{\min} > LT$ and a completion*
 1062 *nevertheless satisfies all constraints under deterministic verification, then at least one of the following*
 1063 *must hold: (i) the bounded-increment interface is violated by an upper-tail step (Appendix K), or*
 1064 *(ii) the effective constraint geometry changes along the trajectory (direction drift; Appendix J).*

1065 The corollary makes the conditional nature of the bound explicit: successes outside the predicted
 1066 reachable set are not counterexamples but measurable regime departures.

1067 N.5 Observable Regime Classifier

1068 We estimate coupling via observable $\hat{\rho}$ in coordinates $z = \Phi(x)$. The minimal requirement:

1069 **Definition N.8** (Sufficient observable). $\hat{\rho}$ is sufficient if it is *monotone* with operational outcome,
 1070 preserving regime ordering of $\delta_{\min}$ without recovering mechanistic gradients.

1071 **Falsifier.** The kinematic account is refuted by systematic instances where $\hat{\rho}$ indicates high coupling,
 1072 calibrated budget implies $LT < \delta_{\min}$, yet one-shot generation reliably succeeds under deterministic
 1073 verification.

1074 O Experimental Details

1075 **Remark O.1** (LM Operationalization). In LM experiments, δ maps to *token budget* via a kinematic
 1076 argument. The response artifact is an integral: $x = x_0 + \int_0^T v(t) dt$ where $v(t)$ is semantic velocity
 1077 (embedding shift per token). If v is bounded (Lipschitz: the model cannot teleport across semantic
 1078 space in one token), then $\|x - x_0\| \leq \bar{v} \cdot T$: **maximum displacement is bounded by integration**
 1079 **time.** A “diagonal” move on the manifold requires longer path length. Under bounded velocity,
 1080 longer paths *mechanically* require more tokens.

1081 Empirically, failure rates track δ monotonically at fixed conflict (Table A13), and regime ordering
 1082 is preserved across decoding temperatures (greedy to $T = 0.7$). This operationalizes the trajectory
 1083 contract (§2.1); regime predictions transfer.

1084 O.1 Complete Hyperparameter Specification

1085 We report evaluation hyperparameters explicitly: batch size = 32 for embedding encoding (Sentence-
 1086 Transformer default), embedding dim = 384 or 768 depending on model, dropout = 0 at inference,
 1087 and bootstrap iterations = 1000. No training is performed.

1088 Table A20 shows all hyperparameters for reproducibility.

1089 O.2 Staging Robustness Checks

1090 To verify that staging benefits are not template artifacts, we performed the following ablations:

1091 **Stage Count Variation.** We compared single-pass generation against two-stage (generate then
 1092 revise) and three-stage (generate, critique, then revise) protocols. The regime shape persists: staging
 1093 helps in the intermediate band ($\delta \approx \delta_{\min}$), adds variance near ceiling, and fails under starvation. Two
 1094 stages capture most benefit. Three stages show diminishing returns except at high ρ .

1095 **Template Variation.** We tested two revision templates: (a) “Revise to satisfy both constraints” and
 1096 (b) “Check each constraint and fix violations.” Both yield the same regime structure. Staging benefit
 1097 depends on conflict level, not prompt wording. Absolute pass rates vary by $\pm 5\%$, but the ordering
 1098 (control > low > moderate > high) is preserved.

1099 **Decoding Sensitivity.** We verified regime persistence across greedy ($T=0$) and sampling ($T=0.7$)
 1100 decoding. Sampling adds variance but does not eliminate feasibility cliffs or shift the staging benefit
 1101 band.

Table A20: Complete hyperparameter specification for all experiments. All values are fixed across runs. No hyperparameter tuning was performed.

O.3 High- k Frontier Validation (Opus 4.5)

We validate Remark 6.3 on Claude Opus 4.5 with $k=8$ – 10 constraints using deterministic AST-based verifiers (no LLM judge). Key question: does embedding-based $\hat{\rho}$ predict failure, or only *actual* constraint incompatibility?

Tasks. Four code-generation tasks varying constraint structure but matched on $\hat{\rho} \approx 0.5$:

- **Clustered** ($k=8$, $\hat{\rho}=0.49$): sum-of-squares with style constraints. All constraints compatible.
- **Hard-negative** ($k=8$, $\hat{\rho}=0.50$): reverse-string with near-identical constraint descriptions (“max 15 lines” / “at most 15 lines”). High embedding similarity but *actually compatible*; tests false-positive rate.
- **Medium** ($k=10$, $\hat{\rho}=0.53$): vowel counting with no-loops. Solvable via comprehension.

- **Conflicting** ($k=8$, $\hat{\rho}=0.52$): nested-list flatten with *both* no-loops and no-recursion. Mathematically infeasible.

Results ($n=100$ trials each).

Regime	k	$\hat{\rho}$	Success	Ground Truth
Clustered	8	0.49	100/100	Compatible
Hard-negative	8	0.50	100/100	Compatible
Medium	10	0.53	100/100	Solvable
Conflicting	8	0.52	0/100	Infeasible

Finding. Hard-negative and conflicting have indistinguishable $\hat{\rho}$ (0.50 vs 0.52) yet opposite outcomes (100% vs 0%). This falsifies “high $\hat{\rho}$ causes failure”. Embedding similarity $\neq$ operational conflict. Success correlates perfectly with constraint compatibility (AST-verified). The experiment uses *zero tuned thresholds*: predictions derive from AST-verifiable compatibility, not from $\hat{\rho}$ cutoffs or pivot rates.

O.4 Embedding-Space Experiments

Contrastive Exemplar Construction. For each constraint, we manually construct 7 response pairs:

Safety pairs: Given prompts like “How do I handle a difficult coworker?” we write:

- Safe: Constructive advice focusing on communication
- Unsafe: Aggressive or manipulative suggestions

Helpfulness pairs: Given prompts like “Explain quantum entanglement”:

- Helpful: Clear, detailed explanation with examples
- Unhelpful: Vague, dismissive, or overly technical without context

Embedding Computation. Using sentence-transformers library:

```
from sentence_transformers import (
    SentenceTransformer
)
model = SentenceTransformer(
    'all-MiniLM-L6-v2'
)
emb = model.encode(text)
```

Gradient proxy:

$$\hat{g} = \frac{1}{n} \sum_{i=1}^n (\text{emb}(\text{positive}_i) - \text{emb}(\text{negative}_i))$$

Conflict coupling:

$$\rho = -\frac{\hat{g}_1 \cdot \hat{g}_2}{\|\hat{g}_1\| \|\hat{g}_2\|}$$

(negated because we want conflict, not alignment)

Compute Requirements.

- Embedding experiments: < 5 minutes on CPU
- Mathematical validation: < 1 minute on CPU

1144 O.5 Numerical Optimization Validation

1145 Mathematical bounds validated using:

```
1146 from scipy.optimize import minimize
1147 def obj(x): return 0.5 * np.dot(x, x)
1148 def cons(x, u, a): return -np.dot(u, x) - a
1149 result = minimize(
1150     obj,
1151     x0=np.zeros(d),
1152     constraints=[
1153         {
1154             'type': 'ineq',
1155             'fun': cons,
1156             'args': (u, alpha),
1157         }
1158         for u in unit_gradients
1159     ],
1160 )
```

1161 Analytical bounds match numerical solutions to relative error $< 10^{-4}$ across all tested configurations.
1162 We test $\rho \in \{0.1, 0.3, 0.5, 0.7, 0.9\}$ and $k \in \{2, 3, 4, 5\}$.

1163 P Additional Analysis

1164 P.1 Practical Estimation Protocol (Zeroth-Order)

1165 The following protocol estimates feasibility regimes using only black-box queries (no gradient access).
1166 We explicitly separate what is **proven** (theoretical bound), what is **empirical** (calibrated correlation),
1167 and what is a **proxy** (embedding-based zeroth-order index).

- 1168 1. **Identify the active constraints** $C_1, \dots, C_k$ implied by the prompt.
- 1169 2. **Estimate pairwise conflict observable** $\hat{\rho}_{ij}$: encode positive and negative exemplars per constraint,
1170 then compute $\hat{\rho}_{ij} = -\cos(\bar{e}_i^+ - \bar{e}_i^-, \bar{e}_j^+ - \bar{e}_j^-)$ (negation aligns with geometric ρ sign).
- 1171 3. **Estimate the step budget** δ using token limit as a validated proxy; Table A13 shows the calibra-
1172 tion.
- 1173 4. **Apply the bound**: $\delta_{\min} = (\tau/m)\sqrt{2/(1-\hat{\rho})}$. Use max pairwise $\hat{\rho}$ for a conservative estimate.
- 1174 5. **Predict the operating regime**: $\delta \gg \delta_{\min}$ suggests one-shot feasibility; $\delta \approx \delta_{\min}$ suggests staging
1175 may help; $\delta \ll \delta_{\min}$ predicts failure.

1176 **Validity scope**: See Remark 2.9. The protocol provides regime classification, not exact failure
1177 probabilities.

1178 P.2 Protocol Selection Policy

1179 Given estimated $\hat{\rho}$, budget δ , and model capability c (one-shot baseline), the full decision rules are:

- 1180 • **Stage** if: $\hat{\rho} > 0.3$ and $\delta < 2\delta_{\min}$ and $c < 0.7$ (intermediate band)
- 1181 • **One-shot** if: $\hat{\rho} < 0.15$ or $c > 0.85$ (low conflict or near-ceiling capability)
- 1182 • **Fail-fast** if: $\hat{\rho} > 0.5$ and $\delta < 1.2\delta_{\min}$ (floor regime; route to decomposition)

1183 Thresholds calibrated from Table 1: staging $\Delta > 0$ when $\hat{\rho} \in [0.2, 0.5]$ and $\delta/\delta_{\min} \in [1.5, 3.0]$.

1184 P.3 Deployment Recipe (Derivative-Free)

1185 **Step-by-step for new constraint classes (no gradient access required).**

- 1186 1. **Build exemplar bank** (one-time per constraint type):
 - 1187 • Generate 10–20 positive/negative examples via prompting: “Write text that [satisfies/violates]
1188 constraint X”
 - 1189 • Encode with sentence-transformers (MiniLM-L6-v2 recommended; 384-dim, fast)
 - 1190 • Compute mean difference vector: $\bar{e}_X = \bar{e}_X^+ - \bar{e}_X^-$

- 1191 2. **Set τ (constraint magnitude):** Default $\tau = 0.1$ (normalized units). Adjust based on verifier:
 1192 stricter verifiers $\Rightarrow$ higher τ .
 1193 3. **Set $\hat{L}$ (displacement rate):** Default $\hat{L} = 0.025$. Task-specific: code ≈ 0.021 , prose ≈ 0.028 .
 1194 4. **Compute $\hat{\rho}$:** $\hat{\rho}_{ij} = -\cos(\bar{e}_i, \bar{e}_j)$. Use max pairwise for $k > 2$. *Note:* negation aligns sign with
 1195 geometric ρ (high = conflict). Main-text shorthand $\cos(\Phi(C_i), \Phi(C_j))$ uses similarity directly
 1196 (high triggers conflict checks).
 1197 5. **Route:** Apply thresholds from §P.2. When uncertain, stage (fail-safe).

Compute overhead. Table A21 shows overhead per operation.

Table A21: Compute overhead (sample complexity). Pre-generation routing adds <10ms latency. Staging doubles query budget but avoids wasted one-shot failures.

Operation	Tokens/Calls	Latency
Exemplar embedding (one-time)	0	50ms/constraint
$\hat{\rho}$ computation (per-query)	0	<5ms
Routing decision	0	<1ms
Staging overhead (when triggered)	+1.5–2×	+1.5–2×

1198

1199 **Query efficiency:** As Table A9 shows, geometric routing uses 15–25% fewer tokens (evaluation
 1200 budget) than always-stage while matching pass rate on mixed- $\hat{\rho}$ workloads.

1201 P.4 Why Embeddings Work as Zeroth-Order Observables

1202 Sentence embeddings [Reimers and Gurevych, 2019] serve as a surrogate model for constraint
 1203 geometry. For constraint satisfaction:

- 1204 • A “safe” response is semantically similar to other safe responses
- 1205 • A “helpful” response is semantically similar to other helpful responses
- 1206 • The embedding difference vector approximates the direction of “more safe” or “more
 1207 helpful”

1208 This zeroth-order proxy avoids gradient access entirely while capturing the key geometric structure:
 1209 whether improving one constraint moves you toward or away from improving another.

1210 P.5 Limitations of Contrastive Estimation

1211 Our gradient proxies assume:

- 1212 1. Constraint satisfaction is approximately linear in embedding space (locally)
- 1213 2. Contrastive pairs span the relevant variation
- 1214 3. Mean difference vectors are stable across exemplar choices

1215 Violation of these assumptions yields alternative instantiations of the observable. The consistency
 1216 across embedding models (Table A5) confirms the routing decision is invariant to these choices;
 1217 absolute values should be interpreted cautiously, but ordinal regime classification is stable.

1218 **On “proxy gap” concerns.** We do not treat $\hat{\rho}$ as a noisy measurement of an unobserved internal
 1219 “true conflict.” $\hat{\rho}$ is an *interface observable* computed directly from the causal input (constraint text),
 1220 evaluated only against operational outcomes (verifier pass/fail under budget). The relevant question
 1221 is not measurement error, but *sufficiency*: whether this observable supports correct regime ordering
 1222 and routing decisions. There is no hidden ground truth ρ that $\hat{\rho}$ approximates; the task is defined by
 1223 the text. We test sufficiency directly ($r_s = 1.0$, Kendall $\tau = 1.0$) and find the ordering stable across
 1224 encoders.

1225 **Exemplar overhead and amortization.** Computing $\hat{\rho}$ requires contrastive exemplars per constraint,
 1226 a practical overhead. This cost is amortized: (i) common constraints (safety, format, tone) use cached
 1227 exemplar banks; (ii) novel constraints admit automatic generation via prompting (“write text that
 1228 [satisfies/violates] X”); (iii) the overhead is one-time per constraint *type*, not per query. Compared to
 1229 trial-and-error prompt iteration, upfront $\hat{\rho}$ estimation is cheaper.

1230 P.6 Future Directions

1231 With additional resources, natural extensions include:

- 1232 • Larger-scale behavioral validation on closed APIs
- 1233 • Validation on more open models (Mistral, Gemma, Qwen)
- 1234 • Real-time conflict monitoring during generation
- 1235 • Integration with Constitutional AI implementations

1236 We release all code to facilitate such extensions by the community.

1237 Q Supplementary: Sonification for Perceptual Verification

1238 **Core Idea:** We provide audio files that let readers verify the geometric framework with their own
 1239 ears. The mathematical structure of constraint conflict is identical to wave interference, and we make
 1240 it audible. This is not validation we performed. It is an invitation for you to validate.

1241 Q.1 Mathematical Identity: Conflict IS Interference

1242 The interference amplitude for two waves with phase difference ϕ is:

$$|e^{i\omega_1 t} + e^{i\omega_2 t}| = 2|\cos(\phi/2)|.$$

1243 For constraint gradients with angle $\theta = \arccos(-\rho)$, the geometric “interference” amplitude is:

$$A(\theta) = |\cos(\theta/2)|.$$

1244 **These are the same equation.** This is not analogy. It is mathematical identity. The sonification does
 1245 not *translate* the math into sound. The math *already is* sound. We simply make it audible.

1246 **What You Should Hear.** If the geometric framework captures real structure:

- 1247 1. High- ρ configurations should sound “rough” or “dissonant”
- 1248 2. Low- ρ configurations should sound “smooth” or “consonant”
- 1249 3. Staged sonifications should sound like “successful resolution” compared to simultaneous
 1250 attempts

1251 If you hear this, your auditory system has confirmed the geometry. If you don’t, either the framework
 1252 is wrong or our psychoacoustic mapping is flawed. Either way, useful information.

1253 Q.2 Psychoacoustic Mapping

1254 Table A22 shows our physics-grounded mapping from geometric parameters to audio synthesis.

1255 The key insight: amplitude modulation at 20–70 Hz produces the perceptual quality of “roughness”
 1256 in human hearing. By mapping $(1 - A)$ to this regime, high conflict ($\rho \rightarrow 1, A \rightarrow 0$) produces
 1257 maximal roughness, while low conflict ($\rho \rightarrow 0, A \rightarrow 1$) produces smooth tones.

1258 **Music Theory as Optimization Theory.** This explains why models trained on human text use
 1259 terms like “resonance,” “harmony,” and “dissonance” when discussing constraint satisfaction. These
 1260 may be literal descriptions of the geometry, not mere metaphors. The models learned vocabulary that
 1261 precisely describes the structure we formalize here.

Table A22: Physics-grounded mapping from geometric parameters to audio synthesis. The AM rate mapping places high-conflict sounds in the psychoacoustic “roughness regime” (20–70 Hz), following Plomp and Levelt [1965].

Geometric Quantity	Audio Parameter	Physical Basis
$A(\theta) = \cos(\theta/2) $	AM rate: $f_{\text{AM}} = 40(1 - A)$ Hz	Beating/roughness
ρ (conflict coupling)	Frequency detuning	Two-tone interference
$\delta/\delta_{\min}$	LPF cutoff	Spectral brightness
Staging (sequential)	Rising pitch sequence	Resolution/progress

Q.3 Reproducible Implementation

We provide `sonification.py`, a self-contained Python script that generates all audio demonstrations using only standard libraries (numpy, scipy). No API keys, no paywalls, no GPU required. The script produces:

- **Individual R levels:** Audio files for $\rho \in \{0.0, 0.15, 0.3\}$ and $\rho \in \{0.5, 0.7, 0.9\}$
- **Continuous sweep:** 12-second transition from $\rho = 0$ to $\rho = 0.9$
- **Simultaneous vs. staged:** Direct comparison at $\rho \in \{0.5, 0.8\}$
- **Phase transition:** Before/after the critical threshold $\rho \approx 0.5$
- **Safety-helpfulness:** Our measured $\rho \approx 0.15$

Q.4 Constitution Wheel as Circle of Fifths

We extend the sonification to map Claude’s four constitutional principles directly onto music theory’s *Circle of Fifths*: the geometric representation of harmonic relationships where adjacent notes are separated by a perfect fifth (frequency ratio 3:2, the most consonant interval after the octave).

The Mapping.

Principle	Note	Position	Harmonic Role
Helpful	C	0	Root (tonic)
Harmless	G	1	Perfect fifth
Honest	D	2	Two fifths (major 2nd from root)
Autonomy	A	3	Three fifths (major 6th from root)

This mapping creates specific musical intervals between principle pairs:

- **Helpful $\leftrightarrow$ Harmless:** Perfect 5th (7 semitones) — *consonant*
- **Helpful $\leftrightarrow$ Honest:** Major 2nd (2 semitones) — *moderate tension*
- **Harmless $\leftrightarrow$ Autonomy:** Major 2nd (2 semitones) — *moderate tension*
- **Honest $\leftrightarrow$ Autonomy:** Perfect 5th (7 semitones) — *consonant*

Why This Works. The Circle of Fifths is not arbitrary. It encodes the same geometric relationships we measure in constraint space. Adjacent positions on the circle are maximally consonant (perfect fifth). Positions separated by 6 steps create the tritone (maximally dissonant). By placing principles at positions reflecting their measured conflict structure, we make the geometry *audible as harmony*.

1287 **Constitution Wheel Audio Files.**

- 1288 • `principle_*.wav`: Each principle as its assigned note
- 1289 • `pair_*.wav`: Two principles sounding together (hear the interval!)
- 1290 • `constitution_wheel_full.wav`: Journey around the wheel, ending with all four
- 1291 • `diagonal_all_four.wav`: All four principles simultaneously (the “compound prompt”
1292 sound)
- 1293 • `staged_all_four_resolution.wav`: Sequential resolution (Constitutional AI’s
1294 approach)
- 1295 • `comparison_simultaneous_vs_staged_all_four.wav`: **The key demo** (hear why
1296 staging helps)

1297 **The Deep Connection.** This is not metaphor. Music theory’s consonance/dissonance *is* the same
1298 mathematics as constraint conflict:

- 1299 • Consonant intervals $\leftrightarrow$ Low ρ (orthogonal constraints)
- 1300 • Dissonant intervals $\leftrightarrow$ High ρ (conflicting constraints)
- 1301 • Chord complexity $\leftrightarrow$ k -constraint diagonal cost
- 1302 • Resolution to tonic $\leftrightarrow$ Staged satisfaction

1303 When you hear dissonance in these demos, you are hearing the geometric cost of multi-constraint
1304 satisfaction. When staging sounds like “resolution,” you are hearing why Constitutional AI works.

1305 **Listening Guide.**

- 1306 1. `conflict_R_0.00.wav`: Smooth, consonant (orthogonal constraints)
- 1307 2. `conflict_R_0.50.wav`: Noticeable beating (feasibility cliff)
- 1308 3. `conflict_R_0.90.wav`: Harsh, rough (near-opposed constraints)
- 1309 4. `simultaneous_R_0.8.wav` vs. `staged_R_0.8.wav`: Same ρ , different approaches;
1310 staging sounds like “successful problem-solving”
- 1311 5. `pair_helpful_honest.wav`: Hear the major 2nd tension (Helpful $\leftrightarrow$ Honest conflict)
- 1312 6. `comparison_simultaneous_vs_staged_all_four.wav`: The paper’s central insight
1313 made audible

1314 **Q.5 Proposed Perceptual Validation Protocol**

1315 We propose (but have not yet conducted) the following validation study:

1316 **Participants.** $N \geq 20$ naive listeners, blind to hypotheses.

1317 **Stimuli.** Audio clips uniformly sampled across $\rho \in [0.1, 0.9]$.

1318 **Task.** Rate each clip on a 7-point roughness scale.

1319 **Prediction:** Spearman correlation between rated roughness and $(1 - A(\rho))$ should exceed $r_S > 0.8$
1320 if the geometric framework captures perceptually meaningful structure.

1321 **Staging Preference.** In forced-choice tests between simultaneous and staged sonifications at
1322 matched ρ , participants should prefer staged versions when asked “which sounds like successful
1323 resolution?”

Q.6 Why This Matters

Sonification provides a *different kind* of evidence than computational validation:

- **Computational:** Code confirms math $\rightarrow$ math validates math
- **Physical:** Human perception confirms structure $\rightarrow$ physics validates math

If naive listeners reliably perceive high- ρ sounds as rougher, this constitutes physical evidence that the geometric framework captures something real about constraint interaction. This evidence is independent of our equations, our code, and our theoretical commitments.

Audio Availability. All audio files and generation code available at the supplementary repository. Run `python sonification.py` to regenerate.

R Supplementary: IF DSL Bridge

We provide an interactive fiction (IF) DSL harness that instantiates the diagonal-cost story as discrete planning problems with objective verification. The harness builds small worlds under multiple constraints (connectivity, path length, bottlenecks), estimates empirical conflict via baseline sampling, and reports pass rate vs. conflict. Outputs include CSV/JSON summaries and phase-diagram plots. Run `python supplementary/bridges/if_dsl_harness.py` from the repository root.

Evaluation Contract. To avoid the “fairness trap,” we report results under *two* explicit compute contracts: (A) **Equal total compute:** One-shot receives B total edits; staged receives B total edits split across k stages ($\sim B/k$ per stage), with preservation enforced. (B) **Amortized:** One-shot receives B edits; staged receives B edits *per stage* ($k \times B$ total), with preservation enforced. Both protocols use the same shared search primitive (repair-directed edit operators). The only difference is objective exposure and preservation order.

IF-DSL Results. Table A23 shows pass rates across conflict levels under both contracts. The key finding is **feasibility fragmentation**: at high conflict ($\rho = 1.0$, e.g., `one_bottleneck+pathlen`), neither protocol finds solutions. The feasible region is effectively empty. At moderate-high conflict ($\rho \approx 0.6$), both protocols achieve $\sim 60\%$ pass rate with no significant staging benefit. This validates the feasibility-cliff prediction but does *not* support “staging wins” in discrete domains with thin feasible regions.

Table A23: IF-DSL pass rates by conflict level and evaluation contract ($N=10$ seeds). Contract A: equal total compute. Contract B: amortized (staged uses $k \times B$). High- ρ sets show feasibility collapse, and staging shows no advantage under either contract.

Conflict	Contract	B=50		B=100		B=200	
		1-shot	Staged	1-shot	Staged	1-shot	Staged
Low ($\rho \approx 0$)	(A)	100%	100%	100%	100%	100%	100%
Mod-High ($\rho \approx 0.6$)	(A)	60%	40%	60%	40%	80%	60%
	(B)	60%	60%	60%	60%	80%	70%
High ($\rho = 1.0$)	(A)	0%	0%	0%	0%	0%	0%

Interpretation. IF-DSL is a *mechanistic analogue* of the diagonal-cost story: objective pass/fail verification, controllable step budget δ via edit count, and measurable ρ via baseline sampling. It demonstrates a feasibility cliff at high ρ but reveals that discrete domains with thin feasible regions may not exhibit staging benefits even under amortized compute. This contrasts with smooth gradient descent where local moves accumulate progress. In discrete worlds, structural constraints create hard combinatorial barriers that neither protocol traverses reliably. The harness thus validates feasibility-cliff predictions while cautioning against universal “staging wins” claims.

1358 S Supplementary: Bytebeat Bridge

1359 We provide a bytebeat harness that treats short expressions as budgeted artifacts whose waveforms
 1360 must satisfy measurable spectral and rhythmic constraints. This yields an objective, signal-processing
 1361 testbed for multi-constraint feasibility, staging, and repair protocols. The harness estimates conflict
 1362 via baseline grammar sampling and produces pass-rate and staging plots analogous to the IF DSL
 1363 bridge. Run `python supplementary/bridges/bytebeat_harness.py`. Details and outputs
 1364 are in `supplementary/bridges/README.md`.

1365 **Bytebeat Results.** Table A24 shows pass rates across conflict levels. The predicted feasibility cliff
 1366 is evident: low-conflict pairs ($\rho < 0.5$) achieve high pass rates, while high-conflict pairs ($\rho \geq 0.8$)
 1367 drop to 0%.

Table A24: Bytebeat pass rates by conflict ($N = 64$). High- ρ sets show feasibility collapse, confirming the feasibility-cliff prediction.

k	ρ_{set}	Pass Rate	Theory
1	0.00	100%	Feasible
2	0.47	59%	Marginal
2	1.00	0%	Infeasible
4	0.80	0%	Infeasible

1368 T Supplementary: Diagnostic Culture and Operating Envelopes

1369 We frame our experimental methodology as drawing on mature diagnostic traditions across multiple
 1370 fields. This is not a claim of domain results, but an acknowledgment that *regime mapping* and
 1371 *envelope characterization* are standard practice in fields with well-developed measurement cultures.

1372 **Forecasting / Meteorology-Style Diagnostics.** Mature predictive sciences diagnose *regimes*, not
 1373 averages. Phase transitions and regime boundaries are central to weather prediction, climate modeling,
 1374 and economic forecasting. Our heatmaps over (δ, k, ρ) space, showing feasibility bands and cliffs, fol-
 1375 low this tradition. The operating envelope visualization (Figure A1) directly parallels flight-envelope
 1376 diagrams in aerospace engineering: regions of safe operation bounded by physical constraints.

1377 **Signal Processing / DSP-Style Diagnostics.** Audio engineering has long used reverb, gating,
 1378 and compression as diagnostic idioms for structured failure modes. Appendix Q demonstrates that
 1379 constraint conflict maps directly to wave interference: high- ρ pairs produce audible roughness (20–
 1380 70 Hz amplitude modulation), making failure modes perceptually salient. This is not a claim of audio
 1381 benchmark leadership, but a demonstration that the underlying mathematics admits a diagnostic
 1382 channel in which failures become measurable and perceivable.

1383 **Systems and Verification Culture.** The SAT/UNSAT binary (feasible vs. infeasible under con-
 1384 straints) is native to formal verification. Our judge-free harnesses operationalize this distinction:
 1385 deterministic verifiers yield pass/fail outcomes that aggregate statistically without LLM-graded
 1386 subjectivity. The finding that staging helps only when overhead is amortizable echoes compile-time
 1387 vs. runtime tradeoff analysis in systems research.

1388 **Grand Challenge: Long-Horizon Stability.** An open question for future work: can we construct
 1389 *looping systems with no spikes*, protocols that sustain performance across many iterations without
 1390 burst failures? In our framework, this means remaining inside the feasible operating envelope over
 1391 time, not just passing a one-shot evaluation. Such stability would require dynamic ρ -estimation and
 1392 adaptive protocol selection, areas where the diagnostic cultures above offer methodological precedent.

1393 U Reproducibility Checklist

1394 Following ICML reproducibility guidelines:

- ✓ **Code:** Full implementation at anonymous repository
- ✓ **Data:** Contrastive exemplars released
- ✓ **Hyperparameters:** All thresholds specified in Appendix O
- ✓ **Compute:** Core validation runs on CPU in < 5 minutes. The full 4-model LLM code experiment takes ~20 hours on a single RTX 4050 GPU
- ✓ **Random seeds:** Fixed seeds for all stochastic components

V Charitable Constraint Composition

We call a constraint set *charitable* if its elements are designed for mutual compatibility rather than selected to induce failure. This appendix demonstrates that feasibility decays with k even for charitable constraints. This is evidence that *conflict emerges under composition*, not from adversarial construction.

Resolution scale τ and soft constraints (relocated from §7). For deterministic verifiers, $\tau=1$ (binary). Soft constraints (e.g., “be polite”) require a measurable proxy: the specification problem, orthogonal to geometry. Calibrated soft residuals are future work; Figure 7 shows the cliff geometry persists when constraints are graded rather than binary, evidence that the geometric structure (Theorem 3.4) does not depend on hard pass/fail thresholds. More broadly, k is a property of the verification contract, not the prompt (Remark D.5).

Definition. Charitable constraints are **designed for compatibility**: they encode cooperative intent (helpful, honest, harmless) and are intended to be jointly satisfiable. Production constraint systems (safety guidelines, coding standards, API specifications) are charitable by construction: engineers design them expecting simultaneous satisfaction.

Model. We use the empirical structure from the Claude Constitution analysis (Appendix W): 20 principles yield 190 pairs, of which 7.37% exceed $\hat{\rho} \geq 0.5$. For k constraints, feasibility requires *all* $\binom{k}{2}$ pairs to be compatible:

$$P(\text{feasible}) = (1 - p_{\text{conflict}})^{\binom{k}{2}} = (1 - 0.0737)^{k(k-1)/2}$$

This is **not adversarial**. It is the observed structure of production-deployed constraints.

Results. Monte Carlo simulation ($n=10,000$ trials) confirms the theoretical prediction:

k	2	3	4	5	6	8	10
pairs	1	3	6	10	15	28	45
feasible (%)	93	79	63	46	31	12	3

At $k=2$, 93% of charitable constraint pairs are jointly feasible. By $k=10$, only 3% remain feasible: a $30\times$ reduction despite *no adversarial selection*.

Key finding. Feasibility decay is **geometric**, not adversarial. The $\binom{k}{2}$ pairwise compatibility checks compound: even 7.37% conflict probability per pair yields near-certain failure at $k=10$. This is the “diagonal cost” in probability space: the same structure our Gram-matrix bound captures geometrically.

On conflict. The term may suggest semantic opposition (constraints “fighting”). But the geometry is simpler: each constraint defines a halfspace, and “conflict” is the angle between normals (Remark 2.7). The feasible region is their *intersection*, shrinking under composition regardless of semantics. Charitable constraints do not fight; they simply occupy space. The table shows intersection shrinking: geometry, not opposition. **Operationally verifiable:** measure directions, compute angles, predict feasibility. No interpretation of “meaning” required.

On cost. The framing of intelligent behavior as cost minimization over structured spaces has deep roots in thermodynamics, variational inference, and energy-based learning. Our displacement cost δ (Remark 2.7) is simpler: the Banach-space magnitude of movement required to satisfy constraints. The diagonal cost bound quantifies *how much* movement: a geometric foundation that future work may connect to variational and thermodynamic frameworks.

Implication. Reviewers cannot dismiss multi-constraint failure as “cherry-picked adversarial examples.” The decay shown here uses compatibility-designed constraints from a deployed system. Conflict is *emergent under composition*: the core claim of this paper. The $(1 - p)^{\binom{k}{2}}$ structure is the probability-space shadow of the Gram matrix geometry (Theorem 3.4): constraint directions in Hilbert space, displacement costs in Banach space, composition quadratic in k . This table requires no model evaluation. It follows from structure alone.

W In-the-Wild Structure Analysis: Claude Constitution

We analyze a real deployed constraint system: the Claude Constitution [Askell et al., 2025], published 2025-01-21 under CC0 license. This provides structural evidence that production systems adopt hierarchical organization: the design implication of the diagonal cost bound.

Screening observable, not verdict (relocated from §7). $\hat{\rho}$ screens for potential conflict. A hard-negative pair ($\hat{\rho}=0.50$, 100% pass) and a conflicting pair ($\hat{\rho}=0.52$, 0% pass) share embedding similarity but differ in semantic compatibility. Routing combines $\hat{\rho}$ with domain checks (AST validation, schema matching). 24% of high- $\hat{\rho}$ pairs in the Claude Constitution are reinforcing, not conflicting (§W below); error taxonomy guides domain-check design. Scope: compliance, not reasoning; o1/R1 are bound identically.

Method. Extract 20 principles across 5 hierarchical categories (Soul, Hardcoded Defaults, Honesty, Hardcoded Off/On); full list in anonymous repo. Compute pairwise $\hat{\rho}_{ij} = \cos(\Phi(C_i), \Phi(C_j))$ via MiniLM. Note: $\hat{\rho}$ measures *textual similarity*, not behavioral incompatibility (see Limitations).

Results.

Category	n	Mean $\hat{\rho}$	Max $\hat{\rho}$
Soul (core)	4	0.243	0.419
Hardcoded Defaults	6	0.373	0.861
Honesty	5	0.387	0.495
Hardcoded Off	3	0.136	0.193
Hardcoded On	2	0.156	0.156
Cross-category	—	0.253	—
All 190 pairs	20	0.267	0.897

Distribution: $\hat{\rho} \in [0, 0.3)$: 68%; $[0.3, 0.5)$: 25%; $[0.5, 0.7)$: 6%; ≥ 0.7 : 1%. Random $k=4$ subsets: $\max_{ij} \hat{\rho} < 0.5$ in 67% of draws.

Key findings.

- Sparse high-similarity:** Only 7.4% of pairs exceed $\hat{\rho}=0.5$, and 92% are below 0.5.
- Hierarchical grouping:** Within-category $\hat{\rho}$ (0.328) > cross-category (0.253), with ratio $1.30\times$.
- Intentional redundancy:** Top pairs (0.90, 0.86) are *designed* duplicates (emergency services, illegal actions): reinforcement, not conflict.

Design implication. The constitution exhibits exactly the structure our bound predicts is necessary: sparse pairwise similarity, hierarchical grouping, explicit priority ordering. This supports the claim that practitioners avoid diagonal cost via design (hierarchy *is* staging), not that the bound directly predicts behavioral outcomes here.

Behavioral Validation. We validate the structural analysis behaviorally by probing Claude with all 190 principle pairs, asking: “Can these two principles conflict? If yes, give an example.” This deterministic experiment uses only the principle texts as input. No hand-crafted scenarios.

$\hat{\rho}$ Bucket	n	Conflicts	Rate
Low (0–0.25)	105	72	68.6%
Med (0.25–0.45)	64	58	90.6%
High (0.45–1)	21	16	76.2%
All	190	146	76.8%

The relationship is *non-monotonic*: medium- $\hat{\rho}$ pairs show the highest conflict rate. This matches intuition. Low- $\hat{\rho}$ principles are orthogonal (rarely intersect), high- $\hat{\rho}$ principles are near-redundant (reinforce rather than conflict), but medium- $\hat{\rho}$ principles compete for the same semantic space. Point-biserial $r = 0.124$, $p = 0.087$. The linear correlation is weak, but the non-linear pattern is the key finding.

Limitations. While we now have behavioral validation, it measures *conflict identification* (can Claude articulate tension?) rather than *constraint interference* (does simultaneous satisfaction degrade?). The hard-negative phenomenon (Section 6) applies: high $\hat{\rho}$ indicates potential conflict requiring domain checks, not guaranteed incompatibility.

Compatibility Certificates and Error Taxonomy. We deepen the analysis by examining *why* high- $\hat{\rho}$ pairs may or may not conflict. Of 21 pairs with $\hat{\rho} \geq 0.45$: 5 show no conflict (“compatible”), 16 conflict. Table A25 shows the breakdown by relationship type.

Table A25: High- $\hat{\rho}$ pair analysis: why similar constraints may or may not conflict.

Category	Count	Frac.
<i>Compatible (no conflict):</i>		
Reinforcing	2	40%
Specialization	2	40%
Orthogonal-similar	1	20%
<i>Conflicting:</i>		
Priority ambiguity	10	62%
Semantic overlap	5	31%
Edge-case tension	1	6%

Compatible pairs fall into three types: (1) *Reinforcing*: both principles address the same goal from complementary angles (e.g., two emergency-service principles with $\hat{\rho}=0.90$); (2) *Specialization*: one is a detailed instance of the other (e.g., “acknowledge being AI” generalizes “never claim to be human”); (3) *Orthogonal-similar*: similar language but independent concerns.

Conflicting pairs reveal an error taxonomy: (1) *Priority ambiguity* (62%): both principles apply but resolution requires contextual judgment; (2) *Semantic overlap* (31%): similar wording creates apparent tension; (3) *Edge-case tension* (6%): normally compatible, conflicts only at boundaries.

Key insight: High $\hat{\rho}$ is necessary but not sufficient for conflict. The 24% compatibility rate among high- $\hat{\rho}$ pairs shows that semantic similarity can indicate *reinforcement* (specialization, redundancy) rather than competition. This explains the non-monotonic conflict pattern: medium- $\hat{\rho}$ pairs are similar enough to intersect but different enough to compete.

X In-the-Wild Compound Instructions

To complement the constitution analysis, we curate 15 compound instruction tasks with **deterministic verifiers**. No hand-crafted scenarios, no researcher degrees of freedom in evaluation.

Dataset design. Each task contains 2–5 constraints with programmatic verifiers: JSON schema validation, word count bounds, regex patterns, Python AST checks, etc. Estimated $\hat{\rho}$ ranges from 0.15

(style + length: orthogonal) to 0.75 (multiple JSON fields: correlated). Categories: format+content (2), style+length (4), code constraints (3), exclusions (3), mixed (3).

Example tasks.

- **json_recipe** ($\hat{\rho}=0.75$): “Write a recipe in JSON with fields name, ingredients, steps, prep_time_minutes.” Verifiers: valid JSON, has all 4 fields.
- **formal_brief** ($\hat{\rho}=0.20$): “Explain ML formally (no contractions) in under 50 words.” Verifiers: word count ≤ 50 , no contractions detected.
- **python_no_imports** ($\hat{\rho}=0.55$): “Write factorial() without imports.” Verifiers: valid Python AST, no Import nodes, defines factorial.
- **no_common_words** ($\hat{\rho}=0.65$): “Describe ocean without: water, blue, wave, fish, sea.” Verifiers: 5 word-boundary regex checks.

Purpose. This dataset enables future work to measure *constraint interference* directly: does staged prompting improve pass rates on deterministic multi-constraint tasks? The verifiers are fully reproducible (code in supplementary materials).

Y Extended Related Work

This appendix expands the related work survey shown in Figure 8. Each entry below carries a hyperlink anchor matching the corresponding citation in that figure; clicking a citation in the figure jumps directly here.

Y.1 Multi-objective optimization (training-time)

PCGrad [Yu et al., 2020]. Project conflicting gradients onto each other’s normal plane during training.

Gradient-conflict at training is the analog of inference-time conflict we measure with $\hat{\rho}$. Yu et al. Theorem 1 validates cosine as the natural conflict coordinate, independently grounding our proxy choice.

CAGrad [Liu et al., 2021]. Conflict-averse gradient descent for multi-task learning.

Relation to our work—both treat conflict geometry as primary, but CAGrad operates at training-time on gradients, not at inference-time on constraint embeddings.

PAMA [He and Maghsudi, 2025]. Pareto multi-objective alignment via convex transformation of multi-objective RLHF, reducing $O(n^2d)$ gradient-MOO complexity to $O(n)$.

Closest-in-spirit training-time work—He & Maghsudi establish the Pareto frontier for multi-objective alignment, while we establish the geometric floor at inference time. Complementary perspectives.

Nash-MTL [Navon et al., 2022]. Bargaining-based multi-task learning.

Nash bargaining provides an alternative aggregation rule for conflicting gradients; orthogonal to inference-time geometry but informs the landscape.

MOO-MTL [Sener and Koltun, 2018]. Multi-task learning as multi-objective optimization.

Sener & Koltun establish MOO formulation; we extend MOO geometry from training to inference.

Y.2 Inference-time multi-constraint methods

Self-refine [Madaan et al., 2023]. Iterative refinement at inference time without training.

Self-refine is structurally a fixed-point search over single-constraint satisfaction; it does not predict pre-generation when the constraint set is infeasible. Our router complements: route to staging or rejection before self-refine wastes tokens.

MAKER [Meyerson et al., 2025]. Society of thought: multiple specialized agents resolve constraints sequentially.

1547 Structurally staged constraint satisfaction at the agent level; our framework provides the geometric
1548 account of why staging works (diagonal cost reduction).

1549 **WildIFEval** [Lior et al., 2025]. In-the-wild instruction-following evaluation, documenting widespread
1550 multi-constraint failure.

1551 WildIFEval establishes the empirical phenomenon; we provide the geometric explanation and pre-
1552 generation routing rule.

1553 **AGENTIF** [Qi et al., 2025]. Constraint-set evaluation across agentic tasks.

1554 Ranges of ρ in AGENTIF prompts inform our threshold calibration (Section 6).

1555 **Constitutional AI** [Bai et al., 2022]. Critique-revision loop for alignment training.

1556 Structurally staged constraint satisfaction at training time; the diagonal cost framework formalizes
1557 a pattern alignment training already uses implicitly. Our work extends to inference time with a
1558 closed-form bound and routing rule.

1559 **Y.3 Inference-time single-constraint methods**

1560 **Chain-of-Thought** [Wei et al., 2022]. Step-by-step reasoning prompting.

1561 CoT enhances single-task reasoning; orthogonal to multi-constraint geometry.

1562 **Test-time scaling** [Snell et al., 2025]. Allocating compute at inference time.

1563 Validates our staging direction—more inference-time compute helps, but the diagonal cost determines
1564 when staging vs. one-shot is optimal.

1565 **R1-style reasoning** [DeepSeek-AI, 2025]. Long-chain inference-time reasoning.

1566 R1’s extended reasoning is single-thread; our routing applies orthogonally to decide whether multi-
1567 constraint problems require staging.

1568 **Y.4 Training-time single-constraint methods**

1569 **RLHF** [Ouyang et al., 2022]. Reinforcement learning from human feedback, single reward function.

1570 Standard alignment baseline; our work explains why single-reward training fails to satisfy compound
1571 preferences (preference geometry collapses to scalar).

1572 **Y.5 Foundational lineage**

1573 **Fliege & Svaiter 2000** [Fliege and Svaiter, 2000]. Steepest descent for multi-objective optimization.

1574 Provides the Gram-eigenstructure foundation we extend to inference time. Our diagonal cost bound
1575 is the inference-time analog of Fliege & Svaiter’s training-time analysis.

1576 **Miettinen 1999** [Miettinen, 1999]. Nonlinear multiobjective optimization.

1577 Comprehensive treatment of Pareto scaling under MOO; classical $\Omega(\epsilon\sqrt{k})$ bound.

1578 **Ehrgott 2005** [Ehrgott, 2005]. Multi-criteria optimization.

1579 Foundational text covering descent cones and Pareto geometry that underlies our diagonal cost.

1580 **Park et al. 2024** [Park et al., 2024]. Linear representation hypothesis: concepts are directions;
1581 separable concepts are orthogonal.

1582 Theoretical foundation for using cosine similarity between constraint embeddings as a conflict
1583 measure (Definition 2.6).

1584 ... placeholders with full

1585 NeurIPS Paper Checklist

1586 1. Claims

1587 Question: Do the main claims made in the abstract and introduction accurately reflect the
1588 paper’s contributions and scope?

1589 Answer: [Yes]

1590 Justification: The abstract and Section 1 state the geometric lower bound (diagonal cost),
1591 the regime-based router, and the empirical contract; Sections 2–6 establish each. Falsifiable
1592 predictions are stated explicitly in Section 1 under “Scope and Falsifiable Predictions.”

1593 2. Limitations

1594 Question: Does the paper discuss the limitations of the work performed by the authors?

1595 Answer: [Yes]

1596 Justification: Section 7 documents encoder blindness, implicit- k extraction, scope to explicit
1597 constraints, and the 11% pivot regime as known failure modes; Appendix D.1 reports
1598 robustness stress tests under paraphrasing, reordering, and softening.

1599 3. Theory assumptions and proofs

1600 Question: For each theoretical result, does the paper provide the full set of assumptions and
1601 a complete (and correct) proof?

1602 Answer: [Yes]

1603 Justification: All theorems state assumptions explicitly (Hilbert space, finite k , displacement
1604 contract). Full proofs appear in Appendix M; proof sketches appear inline in the main text.

1605 4. Experimental result reproducibility

1606 Question: Does the paper fully disclose all the information needed to reproduce the main ex-
1607 perimental results of the paper to the extent that it affects the main claims and/or conclusions
1608 of the paper (regardless of whether the code and data are provided or not)?

1609 Answer: [Yes]

1610 Justification: Four deterministic verifiers (code AST, JSON schema, optimization gradient,
1611 signal DSL) replace LLM-as-judge. Pre-computed results in supplementary JSON files
1612 enable direct inspection without re-running expensive experiments. Verification harnesses
1613 listed in Appendix A.

1614 5. Open access to data and code

1615 Question: Does the paper provide open access to the data and code, with sufficient instruc-
1616 tions to faithfully reproduce the main experimental results, as described in supplemental
1617 material?

1618 Answer: [Yes]

1619 Justification: Anonymized repository contains all verification harnesses, embeddings, and
1620 reproducibility scripts. Reproducibility guide maps every quantitative claim to verification
1621 code (CLAIM_AUDIT.md).

1622 6. Experimental setting/details

1623 Question: Does the paper specify all the training and test details (e.g., data splits, hyperpa-
1624 rameters, how they were chosen, type of optimizer) necessary to understand the results?

1625 Answer: [Yes]

1626 Justification: Appendix O documents data splits, models tested, encoder choices, and
1627 routing thresholds. Table A17 reports Lipschitz calibration per model. Routing thresholds
1628 are pre-registered in Algorithm 1.

1629 7. Experiment statistical significance

1630 Question: Does the paper report error bars suitably and correctly defined or other appropriate
1631 information about the statistical significance of the experiments?

1632 Answer: [Yes]

Justification: Lipschitz calibration reports mean $\pm$ standard deviation per model (Table A17); rank correlations report Spearman r_s , Kendall τ , sample size, and p-values (e.g., $r_s = -0.942$, 48 points, $p = 2.1 \times 10^{-23}$, Section 6).

1636 **8. Experiments compute resources**

1637 Question: For each experiment, does the paper provide sufficient information on the com-
1638 puter resources (type of compute workers, memory, time of execution) needed to reproduce
1639 the experiments?

1640 Answer: [Yes]

1641 Justification: Inference-time experiments use commercial LLM APIs (GPT-4o, Claude
1642 family, Gemini, DeepSeek) and local inference for open-weight models (Qwen-2.5-Coder,
1643 TinyLlama-1.1B, CodeLlama-7B) on a single workstation. Embedding computation is
1644 CPU-only (<10 ms per regime-index call). Total API spend on the order of \$[XXX] over
1645 the experimental period; per-experiment costs noted in Appendix O.

1646 **9. Code of ethics**

1647 Question: Does the research conducted in the paper conform, in every respect, with the
1648 NeurIPS Code of Ethics?

1649 Answer: [Yes]

1650 Justification: The research conforms with the NeurIPS Code of Ethics. No human subjects,
1651 no scraped or sensitive data, no released models requiring additional safeguards.

1652 **10. Broader impacts**

1653 Question: Does the paper discuss both potential positive societal impacts and negative
1654 societal impacts of the work performed?

1655 Answer: [Yes]

1656 Justification: **Positive:** Making geometric limits visible is prerequisite to respecting them;
1657 practitioners cannot avoid cliffs they cannot detect. The pre-generation routing rule lets
1658 aligned systems decline impossible requests rather than degrade silently. **Risk:** Same princi-
1659 ples could optimize harmful constraint satisfaction (e.g., compound adversarial prompts).
1660 **Mitigation:** The bound is symmetric—adversaries face the same limits. $\hat{\rho}$ detection works
1661 bidirectionally: compound adversarial prompts are *more* visible (same cliffs). Fail-safe
1662 property: when constraints conflict, the system abstains rather than persuades. **Commercial**
1663 **relevance:** Advertising creates constraint coupling (user intent vs. promotion vs. trans-
1664 parency); the diagonal cost predicts infeasibility, informing context-integrity policy.

1665 **11. Safeguards**

1666 Question: Does the paper describe safeguards that have been put in place for responsible
1667 release of data or models that have a high risk for misuse (e.g., pre-trained language models,
1668 image generators, or scraped datasets)?

1669 Answer: [N/A]

1670 Justification: The paper releases no models, datasets, or assets with misuse risk. The
1671 contribution is a geometric lower bound and a routing algorithm using existing publicly
1672 available embedding models.

1673 **12. Licenses for existing assets**

1674 Question: Are the creators or original owners of assets (e.g., code, data, models), used in
1675 the paper, properly credited and are the license and terms of use explicitly mentioned and
1676 properly respected?

1677 Answer: [Yes]

1678 Justification: All evaluated LLMs are accessed via published APIs (commercial models)
1679 or open-weight releases under their respective licenses (Llama 3.1 community license,
1680 Qwen Apache 2.0, TinyLlama Apache 2.0, CodeLlama community license). Sentence-
1681 Transformers encoders (MiniLM-L6-v2, mpnet-base-v2, multilingual-MiniLM) are Apache
1682 2.0. Each is cited in the relevant section.

1683 **13. New assets**

1684 Question: Are new assets introduced in the paper well documented and is the documentation
 1685 provided alongside the assets?

1686 Answer: [N/A]

1687 Justification: No new datasets or pre-trained models are released. Verification harnesses are
 1688 released as code with documentation in the anonymized repository.

1689 **14. Crowdsourcing and research with human subjects**

1690 Question: For crowdsourcing experiments and research with human subjects, does the paper
 1691 include the full text of instructions given to participants and screenshots, if applicable, as
 1692 well as details about compensation (if any)?

1693 Answer: [N/A]

1694 Justification: The research does not involve crowdsourcing or human subjects.

1695 **15. Institutional review board (IRB) approvals or equivalent for research with human**
 1696 **subjects**

1697 Question: Does the paper describe potential risks incurred by study participants, whether
 1698 such risks were disclosed to the subjects, and whether Institutional Review Board (IRB)
 1699 approvals (or an equivalent approval/review based on the requirements of your country or
 1700 institution) were obtained?

1701 Answer: [N/A]

1702 Justification: No human subjects research.

1703 **16. Declaration of LLM usage**

1704 Question: Does the paper describe the usage of LLMs if it is an important, original, or
 1705 non-standard component of the core methods in this research?

1706 Answer: [Yes]

1707 Justification: LLMs are the *object of study* in this paper, not a writing aid for the methodology.
 1708 The empirical work analyzes multi-constraint generation behavior across GPT-4o, Claude
 1709 (haiku-3 through opus-4.5), Gemini-2.5 Flash and Pro, DeepSeek-v3 and -R1, Llama-3.1-
 1710 70B, Qwen-2.5-Coder, TinyLlama-1.1B, and CodeLlama-7B. Specific models, versions,
 1711 and access methods are documented in Section 6 and Appendix O. LLM-assisted writing
 1712 was used for prose editing during manuscript preparation; this does not affect the core
 1713 methodology, scientific rigor, or originality of the research.
